Dr. V. **Davies** asked the First Lord of the Admiralty the number of officers and men who had been invalided out of the Service during the last three years, for which records were available, suffering from pulmonary tuberculosis; and in how many of these cases the disease had been considered as not attributable to the conditions of service.—Mr. **Davidson** replied: The total numbers of officers and men invalided for pulmonary tuberculosis during the years 1923, 1924, and 1925 were as follows: 1923, 132; 1924, 150; and 1925, 197. The numbers of these cases in which the disease has been considered as *not* attributable to the conditions of Service were as follows: 1923, 128; 1924, 145; and 1925, 192.

### MONDAY, FEB. 22ND.

### *Europeans and Indian Medical Service.*

Mr. **Robert Richardson** asked the Under-Secretary of State for India whether he would inform the House as to the proposals being made by the Government of India with a view to reserving the civil posts of the Indian Medical Service for Europeans.—Earl **Winterton** replied: This matter is still under consideration, and I regret that I am not at present able to make a statement.

### *Tuberculin Tests.*

Lieut.-Colonel **Fremantle** asked the Minister of Agriculture if he could give figures showing the number of milch cattle that had been subjected to the tuberculin test within the past year, and the number that had been reacted.—Sir K. **Wood** replied: There are very few official records of tuberculin tests other than those carried out for the purpose of the Milk (Special Regulations) Order. The number of cows tested for this purpose in 1924 was about 6000, the majority of which had already passed the test on one or more previous occasions, and the number which reacted in that year was 732. In 1925 the number tested and re-tested was nearly 7500, but I am not yet able to state the number of reactors.

### *Small-pox and Vaccination.*

Mr. **Lansbury** asked the Minister of Health whether he was aware that the outbreak of small-pox in the years 1901–02 coincided with an increase in the number of vaccinations performed in consequence of the passing of the Vaccination Act, 1898; and whether he would state the number of cases of small-pox notified in the years 1897, 1898, 1899, 1900, 1901, 1902, 1903, and 1904, and the number of infants vaccinated out of every hundred born in each of those years.—Sir K. **Wood** replied: It is the fact that the total numbers of vaccinations and revaccinations performed during 1901 and 1902 at the cost of the rates was considerably in excess of the numbers in previous years. But, as the primary object of the Vaccination Act, 1898, was to exempt from penalties parents who obtained certificates of conscientious objection to vaccination, this increase cannot, in my right hon. friend's opinion, be attributed to the passing of that Act, but rather to the fact that when small-pox is prevalent, as in 1901–02, it is usually found that large numbers of persons seek the protection afforded by vaccination. As regards the last part of the question, figures are not available showing the number of cases of small-pox notified during the years in question, but the following is a statement giving percentage of vaccinations to births in each of these cases:—

*Percentage of Vaccinations to Births.*—1897, 62·4; 1898, 61·0; 1899, 66·4; 1900, 68·7; 1901, 71·4; 1902, 74·8; 1903, 75·4; 1904, 75·3.

Mr. **Groves** asked the Minister of Health if he would request the committee which he had appointed to report from time to time on matters relating to vaccination, to furnish him in their first Report with replies to the following queries: what is the precise nature of the disease from which vaccine lymph is derived and how is its nature determined; what is a successful and efficient vaccination and for how long can it be guaranteed to remain so; how frequently has it been found possible to repeat vaccination on the same person; what is the relation of the possibility of frequently repeating vaccination to the question of immunity; and what means are recommended for ascertaining whether the immunity afforded by vaccination has lapsed.—Sir K. **Wood** replied: My right hon. friend will communicate these suggestions to the Committee on Vaccination for their consideration.

Mr. **Charles Williams** asked the Minister of Health what steps he was taking to inform the public of the efficiency of vaccination against small-pox, particularly in those areas where there was any sign of this disease.—Sir K. **Wood** replied: It is the duty of the local authorities of areas in which any case of small-pox occurs to urge the importance of vaccination and the efficiency of this method of protection against small-pox, and it is the usual practice of the local authorities to take these steps.

### *Death-rates in India.*

Mr. **Scurr** asked the Under-Secretary of State for India whether he could state the death-rate, adult and infantile, for Howrah for the last five years.—Earl **Winterton** replied: The latest information is as follows: The death-rates per 1000 of the population for all ages were as follows: 1919, 55·1; 1920, 48·5; 1921, 35·3; 1922, 29·8; 1923, 28·8. The rates of infantile mortality per 1000 births registered were: 1919, 303·9; 1920, 391·0; 1921, 281·1; 1922, 250·1; 1923, 263·9.

Mr. SCURR asked the Under-Secretary of State for India the death-rate, adult and infantile, for Cawnpore and cantonment for the last five years.—Earl WINTERTON replied: The latest information is as follows: The death-rates per mille for all ages were:—

*Cawnpore City.*—1919, 63·60; 1920, 60·34; 1921, 48·38; 1922, 41·53; 1923, 40·73.

*Cawnpore Cantonment.*—1919, 31·63; 1920, 23·89; 1921, 23·79; 1922, 15·60; 1923, 13·06. The infantile mortality rates in Cawnpore City per 1000 births registered were: 1920, 531·07; 1921, 580·67; 1922, 450·87; 1923, 405·17; 1924, 470·90. The rates for the cantonment are not available.

Mr. SCURR asked the Under-Secretary of State for India whether he could state the death-rate, adult and infantile, in the city of Calcutta and suburbs for the last five years.—Earl WINTERTON replied: The latest information is as follows: The death-rates per mille for all ages were: Calcutta (including suburbs), 1919, 42·2; 1920, 39·4; 1921, 33·5; 1922, 29·1; 1923, 28·1. Separate figures for the city and suburbs are not available. The rates of infantile mortality per 1000 births registered in Calcutta (including suburbs) were: 1919, 337·0; 1920,* 386·0; 1921, 330·5; 1922, 287·0; 1923, 291·6.

### TUESDAY, FEB. 23RD.

### *Deaths from Gas Poisoning.*

Mr. SCURR asked the President of the Board of Trade whether his attention had been called to the number of deaths occurring in London from gas poisoning; whether he was aware that coal gas in these days was poisonous because it contained water gas, the chief constituent of which was carbon monoxide; and whether, in view of these circumstances, he would cause an inquiry to be made with a view to making regulations for the better security of life.—Sir BURTON CHADWICK (*Parliamentary Secretary to the Board of Trade*) replied: Special provision is made for recording particulars of deaths attributed to poisoning by gas supplied for use by the public. During 1925, in the areas supplied by the three London gas companies, there were 27 such deaths in which either an open verdict or a verdict of accidental death was returned. I am aware that the use of water gas in towns gas increases the proportion of carbon monoxide beyond that found in ordinary coal gas. The hon. Member will be aware that the matter was reported upon in great detail in 1921, and the Government are watching the position most carefully and closely, but at present it is not considered that a further inquiry would serve any useful purpose.

### *Training of Midwives in Scotland.*

Dr. SHIELS asked the Secretary for Scotland, in view of the new regulations for the training of midwives coming into force in May of this year and the difficulty of meeting the full extra costs by increased fees to pupil nurses in the Scottish maternity hospitals, if he would try to secure for Scotland the same grants in aid which were promised for similar hospitals in England and Wales.—Sir J. GILMOUR replied: I regret that I am unable to take the action proposed for the reason stated in my answer to the question put by Captain Wedgwood Benn on Feb. 15th. In view of the interest of Members in this subject, and the difficulty of dealing adequately with it by the method of question and answer, I have had an explanatory memorandum prepared which I am forwarding to the hon. Member and which I should be glad to make available to Members interested. At the same time I fully appreciate the special difficulty with which the maternity hospitals may be faced, and am keeping it in view in considering the report of the Departmental Committee on the hospital position in Scotland.

### *Health of Women Telephonists.*

Mr. SPOOR asked the Postmaster-General if he could give any indication of the general health of women employed in post-office telephone exchanges; and whether any medical statistics were available showing the causes and prevalence of illness.—Sir W. MITCHELL-THOMSON replied: The statistics for 1924, which are the latest at present available, show that the average numbers of days of sick absence for telephonists were: In London, 13·6 days; in provincial districts of England and Wales, 12·2 days; in Scotland, 13·1 days; in Northern Ireland, 12·3 days. The average sick absence of the whole established female staff on the post-office in 1924 was 12·7 days. I regret that no statistics are available of the numbers of days' absence attributable to particular diseases.

---

* The birth registration system is said to have been defective in this year.

# Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

## SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, March 1st.—8.30 P.M., Social Evening. 9.30 P.M., Dr. Gustave Monod: Illustrated address, From Cagliostro to Coué; or, Imagination as a Method of Treatment.

TUESDAY.—8.30 P.M., ORTHOPÆDICS (Cases at 8.15 P.M.). Discussion: Late Results of Operation for Chronic Painful Hip. 8.30 P.M., PATHOLOGY, at the Lister Institute, Chelsea-gardens, S.W. Dr. E. E. Atkin: The Rationale of the Bile-Solubility Test. Mr. P. Bruce White: Some Observations on the Salt Stability of "Rough" Variants. Dr. F. M. Burnet: Experiments on the Influence of Ultra-violet Light and Hydrogen Peroxide on Bacterial Growth. Dr. G. H. Eagles: The Preparation of Toxic Filtrates of the Streptococcus.

WEDNESDAY.—8.30 P.M., SURGERY, MEDICINE, ELECTRO-THERAPEUTICS, THERAPEUTICS. Discussion: The Treatment of Exophthalmic Goitre.

THURSDAY.—5.15 P.M., BALNEOLOGY AND CLIMATOLOGY. Dr. F. G. Crookshank: Airs, Waters, and Places. 8 P.M., OBSTETRICS AND GYNÆCOLOGY. Dr. Herbert Spencer: Carcinoma Adenomatodes Cervicis Uteri. Mr. H. F. Symonds: A Method of Endoscopic Examination of the Uterus, with its Indications. Mr. C. Lane-Roberts: A Case of Pregnancy Complicated by Ureteric Calculus. Dr. G. Strachan: Vaginal Polypi in Infants with a Report of Two Cases. Dr. Gibbon FitzGibbon: A Revised Conception of Antepartum Accidental Hæmorrhage. Dr. Theobald: A Plea for Drastic Reforms in the Teaching and Practice of Midwifery.

*FRIDAY.*—5 P.M., *LARYNGOLOGY* (Cases at 4 P.M.). Discussion: Atrophic Rhinitis. 8.30 P.M., ANÆSTHETICS. *Dr. C. E. Lakin*: Anæsthesia in Relation to Disorders of the Circulation.

SATURDAY.—10.30 A.M., OTOLOGY (Cases at 9.45 A.M.). Sir William Milligan will read a paper. Mr. H. G. Estcourt (introduced by Mr. F. J. Cleminson): Gradenigo's Syndrome. *Demonstration*: Mr. A. R. Fried: Experiments on Ion Action.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, March 2nd.—5 P.M., *Prof. W. W. C. Topley*: *Experimental Epidemiology* (first Milroy Lecture).

*THURSDAY.*—5 P.M. (second Milroy Lecture).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, March 1st, to SATURDAY, March 6th.—Fellowship of Medicine Lecture, at the Medical Society, 11, Chandos-street, W. Thursday, at 5 P.M., Dr. E. P. Poulton: Dyspepsia. Free to all members of the medical profession. —ROYAL EYE HOSPITAL, St. George's Circus, Southwark, S.E. A series of Demonstrations on the Diagnosis and Treatment of Diseases of the Eye. Monday and Friday, at 3 P.M.—WESTMINSTER HOSPITAL, S.W. *Special Course in Bacteriology.* Two-hour sessions twice weekly on Tuesday and Thursday. General Laboratory Methods (Sterilising, Media making, and Staining, &c.). Further information from the Secretary of the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, March 1st.—10 A.M., Surgical Out-patients: Mr. W. E. Tanner. 10.30 A.M., Gynæcological Operations: Mr. A. E. Giles: Throat, Nose, and Ear Operations: Mr. W. Ibbotson. 2 P.M., Medical, *Surgical, and* Gynæcological Clinics, Operations. 6.30 P.M., Venereal Department.

TUESDAY.—2 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics, Operations. 4.30 P.M., Mr. A. Goodwin: Treatment of Vaginal Discharges.

WEDNESDAY.—10.30 A.M., Surgical Operations: Mr. E. Gillespie. 2 P.M., Medical, Eye, and Skin Clinics, Operations. 5.30 P.M., Venereal Department.

THURSDAY.—10.30 A.M., Dental Out-patients: Mr. E. S. Pierrepont. 2 P.M., Medical, Surgical, and Throat, Nose and Ear Clinics, Operations. 5 P.M., Operations.

FRIDAY.—10.30 A.M., Eye Operations: Mr. N. Fleming. 2 P.M., Surgical, Medical, *and Children Clinics*, Operations. 3 P.M., Gynæcological *Clinic*. 6.30 P.M., Venereal Department.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

THURSDAY, March 4th.—5 P.M., Dr. G. V. Anrep: Regulation of the Coronary Circulation (Sydney Ringer Memorial Lecture).

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, March 5th.—4 P.M., *Dr. Dan McKenzie*: The Surgical Anatomy of the Temporal Bone (illustrated by lantern slides).

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.

WEDNESDAY, March 3rd.—Dr. Harrison: Gastric Analysis.

THURSDAY.—4 P.M., Dr. Thursfield: Idiopathic Purpura.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: February–March.

Clinical Lectures and Demonstrations.

Monday, March 1st.—2 p.m., Out-patient Clinic: Dr. Hinds Howell. 3.30 p.m., The Neuro-Muscular System, II., Motor Automatism: Dr. Kinnier Wilson.

Tuesday, March 2nd.—2 p.m., Out-patient Clinic: Dr. Walshe. 3.30 p.m., Syringomyelia: Dr. Hinds Howell.

Thursday, March 4th.—2 p.m., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 p.m., Neuro-Syphilis, II.: Dr. Riddoch.

Friday, March 5th.—2 p.m., Out-patient Clinic: Dr. Adie. 3.30 p.m., The Diagnosis of Muscular Atrophy which is Progressive: Dr. Collier.

The fee for the Course, including Pathology lectures, is £5 5*s.* For those who hold Perpetual Tickets the fee is £3 3*s.*

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 a.m., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. Greenfield, Dean of Medical School.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

Tuesday, March 2nd.—5 p.m., Dr. Wilfrid Fox: Cutaneous Syphilis (2).

Thursday.—5 p.m., Dr. S. E. Dore: Alopecia.

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY.

Wednesday, March 3rd.—8.30 p.m., Mr. F. St. J. Steadman: The Treatment of Overcrowding of the Dental Arches.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

Friday, March 5th.—3.30 p.m. (at the Royal Hospital), Mr. Townrow: Demonstration of Nose and Throat Cases.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

Tuesday, March 2nd.—4.15 p.m., Dr. F. Craven Moore: The Diagnosis of Nephritis.

Friday.—4.15 p.m., Dr. G. E. Loveday: Laboratory Demonstration.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURE.

Friday, March 5th.—4.30 p.m. (at Whitworth-street West Branch), Dr. J. W. Bride: Toxæmias of Pregnancy.

## Appointments.

Eynon, C. M., F.R.C.S. Edin., M.D. Ont., has been appointed Surgeon in Charge of a hospital in connexion with the Welland Canal construction at St. Catherine's, Ontario.

Taylor, R. S., M.B., Ch.B. Liverp., F.R.C.S. Edin., Honorary Surgeon to the Lock Department of the Royal Infirmary, Liverpool.

Sheffield Royal Hospital: Barron, D. C., M.D., Ch.B. Edin., Willey, H. L., M.B., B.Ch. Camb., Holdsworth, C. D., M.D., B.S. Lond., Pleasance, R. E., M.D., Ch.B. Sheff., Paige, E. F., M.B., Ch.B. Sheff., Honorary Clinical Assistants; Imrie, C. G., M.R.C.P. Lond., M.D. Ont., Medical Registrar; Yates, H. Blacow, M.B., B.Ch. Sheff., F.R.C.S., Surgical Registrar; Holmes, E., M.B., Ch.B. Leeds, Resident Surgical Officer; Drs. Everard, Walker, Fawcett, Hatherley, Jago, Sykes, L. Jago, and Flint, Resident Surgical Officers.

Certifying Surgeons under the Factory and Workshop Acts: Young, J. M., M.B., B.Ch. Belf. (Rothwell District of York); MacDiarmid, A. J., M.B., Ch.B. Aberd. (Ryde); Manson, M., M.D., Ch.B. Glasg., D.P.H. (Whitehaven, Cumberland); Firth, I. G. M., M.B., Ch.B. Aberd. (Tenbury, Worcestershire); and Anderson, D. H., M.B., C.M. Edin. (Tunbridge Wells; Smith, R. G., L.R.C.P. Lond., M.R.C.S. (Southend); Mansfield, H. Y., M.D., B.Ch. Camb. (Yarmouth, I.W.); Williams, H. C., M.B., B.Ch. Camb. (Alton); White, R. F., M.B., Ch.B. Bristol (Nailsea, Somerset).

## Vacancies.

*For further information refer to the advertisement columns.*

*Ayr County Hospital.*—Jun. H.S. At rate of £80 for first six months.

*Bath, Winsley Sanatorium.*—Asst. Res. M.O. £250.

*Birmingham General Hospital.*—Part-time Clin. Asst. in Ven. Dept. £350.

*Birmingham, Queen's Hospital.*—H.P., H.S.'s, Cas. H.S., and Res. Anæsthetists. Each £70.

*Bolingbroke Hospital, Wandsworth Common, S.W.*—Res. M.O. £200.

*Buxton, Derbyshire, Devonshire, Hospital.*—Asst. H.P. At rate of £150.

*Central London Ophthalmic Hospital, Judd-street, W.C*—Asst. S.

*Charing Cross Hospital.*—Surg. Reg., Med. Reg. Each £150. Also Obstet. Reg.

*Croydon Mental Hospital, Upper Warlingham, Surrey.*—Asst. M.O. £350.

*Derbyshire Royal Infirmary, Derby.*—Hon. Dental S.

*Dunfermline Burgh.*—M.O.H. £800.

*Essex Administrative County.*—Asst. Tuberculosis O. £700.

*Exeter, Royal Devon and Exeter Hospital.*—H.P. and Asst. H.S. Each at rate of £130.

*Freemasons Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.*—Res. M.O. At rate of £250.

*General Lying-in Hospital, York-road, Lambeth, S.E.*—Res. M.O. At rate of £100.

*Hospital for Epilepsy and Paralysis, Maida Vale, W.*—Hon. Ear, Nose and Throat S.

*Italian Hospital, Queen-square, W.C.*—Hon. Ophth. S.

*Kettering and District General Hospital.*—Res. M.O. At rate of £150.

*Liverpool, Royal Southern Hospital.*—Hon. Asst. S.

*London County Council. Public Health Dept.*—Sen. M.O. £1219 12*s.* 10*d.*

*London Hospital, E.*—Vacancy on Hon. Surg. Staff. Gynæcological Reg. £400.

*Manchester, Royal Children's Hospital, Gartside-street.*—Asst. M.O. At rate of £150.

*Manchester, Royal Children's Hospital, Pendlebury.*—Res. Surg. O. At rate of £80.

*Manchester Royal Eye Hospital.*—Jun. H.S. £120.

*National Hospital for Diseases of the Heart, Westmoreland-street, W.*—Res. M.O. At rate of £150.

*National Hospital for the Paralysed and Epileptic, Queen-square, W.C.*—Med. Reg. £200.

*Northumberland County Council, Wooley Sanatorium, near Hexham.*—Asst. Med. Supt., &c. £600.

*Nottingham General Hospital.*—H.P. At rate of £150.

*Nottingham, Ransom Sanatorium.*—Asst. Res. M.O. £375.

*Oxford, Radcliffe Infirmary and County Hospital.*—Cas. H.S. At rate of £120.

*Plymouth, Homœopathic and General Hospital.*—H.S. £150.

*Plymouth, Udal Torre Sanatorium. Yelverton.*—Res. M.O. £450.

*Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.*—Dist. Res. M.O. At rate of £80.

*Queen Mary's Hospital for the East End, Stratford, E.*—Hon. Asst. Obstet. S.

*Queen's Hospital for Children, Hackney-road, Bethnal Green, E.*—H.S. At rate of £100. Res. M.O. £200. H.P. At rate of £100.

*Richmond, Surrey, Royal Hospital.*—Hon. S. to Out-patients.

*Royal Free Hospital and Lond. Sch. of Medicine for Women, Gray's Inn-road, W.C.*—Sen. Asst. Path. Full-time. £600.

*Royal Northern Hospital, Holloway, N.*—H.S. and Obstet. H.S. Each at rate of £70.

*St. John's Hospital, Lewisham, S.E.*—Res. H.S. At rate of £100.

*St. Mary Abbots Hospital, Marloes-road, Kensington.*—Asst. Res. M.O. £450.

*St. Mary's Hospital, W.*—Second Asst. Pathologist. £250.

*Salford County Borough, Infectious Dis. Hosp., Ladywell Sanat., Pendleton.*—Res. M.O. £350.

*Salford Royal Hospital.*—H.P. and H.S. Each at rate of £125.

*Salisbury General Infirmary.*—H.S. £150.

*Samaritan Free Hospital for Women, Marylebone-road, N.W.*—H.S. At rate of £100.

*Singapore Municipality, Straits Settlements.*—Asst. Health O. £1008.

*Southampton, Royal South Hants and Southampton Hospital.*—Jun. H.S. At rate of £150.

*Stoke-on-Trent, North Staffordshire Royal Infirmary.*—Jun. H.P. £125.

*West London Hospital, Hammersmith, W.*—H.P. and two H.S.'s. Each at rate of £100.

*Western Ophthalmic Hospital, Marylebone-road, N.W.*—Sen. and Jun. H.S.'s. At rate of £150 and £100 respectively.

*Windsor, King Edward VII. Hospital*—Hon. Asst. S.

*York County Hospital.*—H.P. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacancy for a Certifying Factory Surgeon at Caerleon, Monmouth.

## Births, Marriages, and Deaths.

### BIRTHS.

Hearn.—On Feb. 16th, at Buckland-crescent, Hampstead, N.W., the wife of Reginald J. Hearn, M.D., of a daughter.

Oliver.—On Feb. 13th, at Edgefield, St. Peters, Jersey, C.I., the wife of Dr. H. G. Oliver, M.C., of a daughter.

Schlesinger.—On Feb. 16th, at Hollycroft-avenue, N.W., the wife of Bernard E. Schlesinger, M.B., B.Ch., M.R.C.P., of a son.

Wright.—On Feb. 15th, at Warwick Lodge, Warwick-avenue, W., the wife of Dr. E. T. Wright, of a daughter.

### DEATHS.

Derham-Reid.—On Feb. 17th, at his residence, Auchinellan, St. Helens-road, Bolton, Major James Derham Reid, M.C., R.A.M.C. T. (retd.), M.R.C.S. Eng., L.R.C.P. Lond., of Auchinellan, Argyll.

Roberts.—On Feb. 18th, at Southport, Lieut.-Colonel Hugh Jones Roberts, F.R.C.S., D.L., J.P., of "Llywenarth," Penygroes, Carnarvonshire.

Smith.—On Feb. 18th, at St. George's-road, Wimbledon, Surrey, William Woodriff Smith, M.D., in his 82nd year.

Swann.—On Feb. 16th, at Cambridge, from blood poisoning contracted while performing a post-mortem examination, Meredith Blake Robson Swann, M.D., Fellow of Gonville and Caius College, aged 32 years.

*N.B.—A fee 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Comments, and Abstracts.

## SOME MEDICAL INVENTORS.

PATENT offices have for some time been attracting attention, it being felt by authority on both sides of the Atlantic that reform is needed in a sphere where much human endeavour continues to be wasted. In the United States, where it has hitherto been necessary for patentees to present complete models of their inventions with their specifications, it has even been proposed to burn the museum devoted to the display of patents. At the rate that models accumulate in an intensely inventive atmosphere, Washington is in danger of becoming a museum of machines. Hence the proposed holocaust.

### *Sewing-machine and Steam.*

Were this to take place much that is curious would be destroyed, and much designed to promote human welfare. That many of the projectors were medical men goes without saying, for medical men are clever with their fingers and prone to find out short cuts in manipulative procedure. Surgeons have, indeed, invented innumerable instruments and surgical contrivances, but what is not generally known is that medical men have often been what may be called lay inventors. Sometimes their contribution to public utility and the culture-drifts of civilisation has been indirect. Thus William Rawlings Beaumont, M.D., F.R.C.S. (1803–1875), was quite unintentionally the originator of Singer's variant of the sewing-machine. In 1836 he invented a small contrivance for stitching cleft palate, now in the museum of the Royal College of Surgeons, and this, when exhibited in a shop window in New York, caught the eye of Mr. Isaac M. Singer, who adapted its principle to his sewing-machine. Singer made a large fortune. Beaumont, on the other hand, died far from a millionaire. In 1867 he writes to his correspondent, Thomas Madden Stone, secretary of the Royal College of Surgeons of England: "I am obliged to work on at my profession (probably the better for me), tho' it has been but a profitless occupation, for I was really much better off in a pecuniary point of view above 30 years ago than I am now. I made from the first the mistake of not becoming a general practitioner—of not practising midwifery." At the time of writing, although blind of one eye, he was still operating and still the admired professor of clinical surgery at the University of Toronto. It is noteworthy, however, that he says nothing here of his famous observation on gastric digestion in the case of Alexis St. Martin, nor of his numerous inventions. It was left to his clever fussy correspondent, "Tommy" Stone, to boom the surgical sewing-machine in THE LANCET, when he wrote of this instrument as "destined to make an epoch in the world's history." The sewing machine on Singer's plan is, relatively speaking, no great matter, and we ask: What of the major discoveries and inventions? What of steam, for instance? And has there been a medical name in the process of the slow evolution of the steam-engine? It is doubtful, indeed, whether Dr. Peter Chamberlen (1601–83), to whom the invention of the short midwifery forceps is perhaps erroneously attributed, had got hold of the idea of the locomotive engine when, in 1662, he petitioned Parliament for an Act to protect "the new invention of navigating with all winds in a straight line." He had patented this invention in France, the Netherlands, and Venice, and now asked the English Parliament to protect him; but as he refused to show a model of his invention, it is difficult to see what Parliament could protect beyond a secret. Peter Chamberlen's life, wrote Sir Norman Moore, "was one long succession of schemes." In 1618 he sought to institute "public artificial baths" by Act of Parliament. In 1619 he proposed to propel carriages by wind, and his petition of 1662 may refer to these. More probably, however, it has to do with an apparatus for navigating vessels in a straight line in all winds. In 1730 Dr. John Allen patented two inventions which, if they had been carried out, would probably have resulted in the first steam-boat. He proposed to construct an engine for raising water by means of fire, which, when placed in a ship, would force water out of the stern, thus enabling the ship to move in a calm.

### *Shorthand and Sanitation.*

Minor inventions by physicians were noted in 1917 by that careful antiquarian, the late Dr. Samuel Dodd Clippingdale. Thus Dr. Timothy Bright, of Cambridge, was the inventor of modern shorthand as opposed to the lost art described by him in his work, "Characterie" in 1588. Dr. David Bridges, of Hull, in about the year 1780, invented spermaceti candles. Dr. Neil Arnott was the inventor about the year 1832 of a ventilating chimney and a smokeless grate. Traction of barges by horses instead of by men is said to have been introduced by Dr. Battle, of Marlow. The Gatling gun is named after Dr. Richard Gatling, who invented this form of artillery in 1861. And, finally, the guillotine is named after Dr. Joseph Ignatius Guillotin.

These were physicians; the surgeons who have made useful inventions are more numerous.

On reference to the enormous index to the "Roll" of the Fellows of the Royal College of Surgeons of England which, regrettably enough, remains in MS., a respectable list may be made out of what are properly lay inventions due to the genius of surgeons. Proceeding alphabetically from the above-mentioned Rawlings Beaumont we come to Peter Hinckes Bird, F.R.C.S. (1827–61), who in 1863 was the inventor of a "costless system of ventilation." This suggests no more than open windows, though the inventor received several certificates and medals, and the invention was fully described in *The Builder*, March 1st, 1863. Charles Brooke, F.R.C.S. (1801–79), was twenty-third wrangler in 1827, and a most distinguished inventor. He was the author of some improvements in microscopy, but his fame chiefly rests on his barometers, thermometers, psychrometers, and magnetometers, which registered their variations photographically and were known as "self-recording instruments." They were adopted by the Royal Observatories of Greenwich, Paris, and other meteorological stations, and brought their author the premium offered by the Government as well as a council medal at the Great Exhibition of 1851.

Medical men have naturally played a part in sanitary reform, such as the introduction of improved drainage, water-supply, gas-lighting, and so forth. In this sense hosts of little-known practitioners have been innovators, if not inventors. The dress of the City policemen was designed by a surgeon, George Borlase Childs, F.R.C.S., who was born in 1816 and was for many years surgeon-in-chief to the City of London police. He, in fact, in 1861 introduced the helmet as we now know it, and thus emphatically contributed to the *mise en scène* of London streets.

### *Miscellaneous Inventions.*

Surg.-General Saville Marriott Pelly, C.B., F.R.C.S. (1819–93), was the inventor of an electric clock, though this is somewhat overshadowed by his electric stethoscope, which enabled all the members of a class to listen at the same time to one heart. Like many others, Pelly made both lay and medical inventions. Such inventors were George Armstrong Peters, M.B., F.R.C.S. (1839–1907), who invented a self-registering rifle-target, which is named after him; Sir William Rae, C.B., M.D., F.R.C.S. (1786–1873), who invented an apparatus for distilling water; and George Rowell, M.D., F.R.C.S., who died about 20 years ago and was the inventor of a milligrade thermometer. In the same useful category as the policeman's helmet must be classed the sweeping-machine for use in city streets, which we owe to Sir Edwin Saunders, F.R.C.S., the dentist to Queen Victoria (1814–1901). A prolific inventor and remarkable man was Alfred Smee, F.R.C.S., F.R.S. (1818–77), a son of the accountant-general to the Bank of England, who lived in the bank with his father. On the recommendation of Sir Astley Cooper he was appointed surgeon to the bank, Cooper being of opinion that his genius as a man of science might be turned to good account there. He invented Smee's battery, which is named after him, and used for trade purposes. We also owe to him durable writing ink (1813), and the present system of printing cheques and notes at the Bank of England, finally perfected by him in conjunction with two others in 1854, when, as Sir D'Arcy Power says in the "Dictionary of National Biography," "certain modifications were introduced into the manufacture of the notes to prevent or render it impossible any longer to split them." To James Startin, F.R.C.S. (1806–72), otherwise a fertile surgical inventor, we owe a process for stiffening felt hats; and to the famous James Syme, D.C.L. Oxon., M.D., F.R.C.S. (1799–1870), is due water-proofing (caoutchouc in solution applied to the preparation of waterproof cloth). Syme gained nothing by his discovery, which was patented by a Glasgow manufacturer. "Mackintoshes" are, however, not attributed to the patentee in Scotland always, and in France they are called "Macfarlanes," as though their wearers were conscious of some misstatement in the English name. To Robert Temple Wright, M.D., F.R.C.S. (1813–1902), of the Indian Army, is due the vermin-free "Indian Bungalow," the Milver ambulance cart, and various improvements in military kit.

Some inventions of medical men appear humorous. Thus Sir William Petty, professor of anatomy at Oxford and a famous political economist, tickled both Charles II. and Pepys with his invention of a boat with two keels. Dr Francis Moore originated "Old Moore"; and, latterly, William Henry Stone, M.A., F.R.C.S., censor of the Royal College of Physicians in 1884, struck a quaint note with his bassoon capable of uttering a sound lower in the scale than any hitherto emitted.

The attribution of inventions is a delicate matter. Yet it is to the credit of the profession that so few are quarrelled over. Instruments are too often quietly ceded by their medical inventors to the manufacturers and the instrument makers. We can, in a long list, only find one instrument—and that not a surgical one—claimed by two surgeons. Thus, Lund's well-known "corkscrew lever" seems to have been claimed by another. But neither surgeon fought over the matter. Often, too, inventions are, properly speaking, only first thought of by medical men and perfected by others. In the region of ideas such inventions might be called originations. Thus we might have cited Mouat's origination of the Indian universities, and class in the same category John Postgate's initiation of the later legislation against adulteration. John Postgate, F.R.C.S. (1820–81), started life as a grocer's boy, and having observed the tricks of the trade was led into a long campaign against impure food, which terminated in the passing of the Sale of Food and Drugs Act in 1875.

## "SABBIATURA."

OF quite recent years the public have discovered for themselves the sensations of well-being which are to be derived from the warm sand-bath, and at some continental seaside resorts part of the day's sanitary régime consists of being buried and burying others in the hot expanse of the shores. Apart from physical enjoyment the hot sand-bath has properties which have been found useful in the treatment of such conditions as rheumatism, rheumatoid arthritis, neuritis, lumbago, sciatica, and forms of chronic synovitis, the treatment in these directions being specially studied and applied at the little old town of Alassio which is situated on the Italian Riviera, between Porto Mauritzio and Albenga, 23 miles from San Remo, where there is a fine strip of pure silica sands some three miles long. Unlike most places on the Italian Riviera, Alassio has both a winter and summer season, and during the latter period the dress of both sexes mainly consists of bright-coloured towelling with a shady head covering. There is practically no tide, and bathing in the warm water is safe even for children. The sabbiatura, as the hot sand-bath treatment is called, is carried out from the middle of May to the middle of September. A trench is prepared in the early morning and allowed to absorb the full heat of the sun till half an hour before noon when the patient is put into it and covered with the hot, dry sand. Here he remains for half an hour, during which time profuse perspiration takes place; he emerges coated thickly with wet sand. A plunge in the sea closes the sand-bath and washes the skin, and the patient emerges from the water invigorated and with a hearty appetite. A course of baths usually lasts from four to five weeks, but in transient cases of trouble may be shorter, and longer in more obstinate maladies. Medical supervision of these baths is offered at the Villa Iris, beautifully surrounded by a garden of palms and fruit and flowering trees under the shelter of Cape San Croce. Here heliotherapy and physical exercises are carried out all the year round under the direction of Dr. F. A. Barton, the superintendent of the treatment centre.

## MULE-SPINNERS' CANCER.

Dr. Archibald Leitch, director of the Cancer Hospital Research Institute, London, and who was awarded the Manchester Christie Hospital prize for his last year's work, gave an address on mule-spinners' cancer at Manchester University on Feb. 19th. After describing in detail the work already done, he suggested that some of the first research undertaken by the Manchester Cancer Committee might be directed towards the discovery of a harmless non-irritant oil for use in cotton-mills. Until an oil was discovered which did not provoke the disease or until some method had been devised by which the spinner could be kept from contact with the oil, the only remedy for spinners' cancer was to have frequent medical inspection, so that the earliest lesions could be detected at a stage at which the disease could be prevented. A Government committee had been inquiring into the subject and would make its report shortly. The work of the committee was based in the first place on the work, about three years ago, of two Manchester surgeons, Mr. A. H. Southam and Mr. S. R. Wilson, and on information about the incidence of the disease which had been collected by Dr. S. A. Henry, medical inspector of factories. The records of the Manchester Royal Infirmary for 20 years showed that of 141 cases of cancer of the scrotum 69 had occurred in mule-spinners. During the last 50 years Dr. Henry had traced 530 cases of mule-spinners' cancer, the earliest record being in 1887. Yet two or three years ago neither the spinners nor their well-organised union had ever heard of the disease. In the general community the incidence was 4·1 per million; among spinners it was 134 per million; among chimney sweeps 534, and among patent fuel workers 608. There were about 23,000 mule-spinners in the country, and between the ages of 25 and 35 they were 11 times more liable to the disease than other people. From the ages of 45 to 65 their liability was 60 times that of the general population, and from 65 to 85 it was 100 times. The incidence of this form of cancer was not, however, connected with age; it varied with the length of time during which the operative had been subjected to the irritant, and was higher amongst the older men because they had been mule-spinners longer. The average time for the development of the disease was about 40 years. No case was known to have occurred in less than 10 years, and the longest time taken for development was 63 years. Dr. Leitch gave an historical account of the few cases that were discovered amongst tar-workers in Germany, amongst pitch-workers in South Wales, and in the shale oil industries in Scotland—in all about a score of cases in 50 years. The few isolated cases on the Continent were due to contact with crude oil, but the Lancashire cases among mule-spinners were due to contact with refined oils. The disease could be recognised before cancer had actually developed, and if caught in time could be prevented. Sometimes there was a delayed action and a person was not necessarily immune after he had left the trade. All workers were exposed to the oil, but only a very small proportion of them developed cancer. There was no such thing as a special susceptibility. A person might be liable to it at one time and not at another, just as to any other disease, and when once the cancerous stage was reached the only effective remedy was surgical.

## POISONOUS SPIDERS.

THE greater part of the current number of *Memorias do Instituto de Butantan* (1925, Tomo II., Fasciculo Unico, Santo Paulo, Brazil) is taken up by an elaborate and interesting study of poisonous spiders, which are, unfortunately, somewhat numerous on the South American continent and also in various other parts of the world, including some European countries. The Italian tarantula is the most famous of all these pests, and the authors, Dr. Brazil and Dr. Velland, discuss briefly the question of tarantulism, epidemics of which were said to occur in the seventeenth and eighteenth centuries.

After a short historical retrospect, they give the results of their experimental investigation on the venom of several species, with a description of their technique, and describe the different effects, local and general, of the venoms of different species, and the results obtained by inoculation into animals. By the progressive inoculation of sheep they succeeded in obtaining a very active antiserum for the venom of two species and they recommend this method of treatment. There are a number of excellent illustrations, showing the spiders themselves, their poison glands (macroscopically and microscopically), and the lesions produced by them in men and animals. The lesions of some species are extensive local necroses, whilst the venom of others, which are far more deadly, acts mainly on the nervous system and is said to be as potent as that of the more dangerous snakes. There is an extensive bibliography at the end of the article.

## CHRONIC NASAL DISCHARGE IN CHILDREN.

*To the Editor of* THE LANCET.

SIR,—With reference to the article on this subject in THE LANCET (1925, ii., 1132), in which the removal of foreign bodies from the nose is touched on, I should like to call attention to a very simple method that was shown us many years ago at Guy's by Mr. F. J. Steward. An ordinary butterfly-wing grooved director is taken and passed up the nasal cavity more or less parallel to the roof till its point is well above the foreign body; the portion of the director outside the nose is then raised till the point inside the nose is depressed sufficiently to come in contact with the floor; it is then "dragged out" of the nose, the point being kept in contact with the floor all the time, so that the foreign body is expelled in front of it.

Children in these parts not uncommonly push a seed of the Imli tree up their nose; this is about the size of a large "broad bean" and very quickly becomes too soft to be grasped by forceps but is easily removed in the manner described. This method is equally useful in dealing with hard, smooth spherical bodies such as large beads, pebbles, or marbles.

I am, Sir, yours faithfully,
H. WATTS,
Lieut.-Col., I.M.S.

Betul, C.P., India, Feb. 2nd, 1926.

THE new address of the Food Education Society is 24, Tufton-street (Great Smith-street), Westminster, S.W. 1. Tel.: Victoria 7145.

### THE FIRST (1926)

# Milroy Lecture

### ON

# EXPERIMENTAL EPIDEMIOLOGY.

*Delivered before the Royal College of Physicians of London on March 2nd*

By W. W. C. TOPLEY, M.D. Camb., F.R.C.P. Lond.,
PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF MANCHESTER.

The section of the Founder's "Suggestions" which justifies me in bringing to your notice the experiments which I propose to describe is, I think, worth quoting, for it shows the breadth of his outlook on the problems of preventive medicine. Written in 1877, it runs as follows:—

> "As there is good reason to believe that the science of Human Pathology would be profitably advanced by a better knowledge, than is possessed by most medical men in this country, of the diseases of the lower animals, and especially of domesticated animals, I would suggest that the occasional examination of various topics relating to Epizootics and to general Comparative Pathology might possibly be introduced with advantage as a subject for a few lectures.
>
> "In the present day, when we hear so much about various spreading Epizootics, respecting the origin and modes of the diffusion and the distribution of which there appears to be considerable diversity of opinion among educated Veterinary practitioners, it might be desirable, as it seems to me, that the evidence collected by competent Veterinarians from a sufficient number of well-verified data, should, in the interests of Science and of the public welfare, be from time to time weighed and sifted by medical men who have paid special attention to the study of the course of epidemics among the human race, in order to determine whether the natural laws which regulate or affect the development and progress of the two classes of morbid phenomena are analogous, or otherwise. Such comparative scrutiny could scarcely fail to advance the cause of general scientific truth, and would serve also to the elucidation of sound principles for the guidance of safe prophylactic and preventive legislation."

I have departed from the letter of the Founder's injunction only in selecting as material for study small laboratory animals, which can be bred and observed under strictly controlled conditions, so replacing the method of simple observation by the method of experiment. From its spirit I do not think that I have departed at all.

The view which Dr. Milroy expressed 50 years ago, that the diseases of man and animals should be studied in close relation to one another, has steadily gained adherents. The liaison between human and veterinary pathology, which has developed so rapidly in recent years, will, I believe, lead to a rapid advance in our knowledge of disease in general and of infective processes in particular. In this country we owe a great debt to the late Sir Clifford Allbutt for his persistent advocacy of the more thorough study of comparative pathology. The problems of epidemiology, of the incidence of disease on herds rather than on individuals, have attracted many of the masters of medicine. The subject is intrinsically interesting as a purely biological problem, and it touches so closely the future welfare of the human species that it cannot be ignored by any who are concerned with the development of our social organisation.

It would take too long to discuss in any detail the different methods of approach towards the main problems of epidemic disease, which have been followed by investigators in the past; moreover, this question has recently been dealt with elsewhere. I should like, however, to record my personal conviction that our present lack of knowledge is largely the outcome of faulty methods of inquiry. If it be true, as I believe, that the origin and spread of any epidemic of microbial infection depends upon variations in the normally existing relations between living organisms, and that the actual outbreak of disease, the occurrence of clinically recognisable cases, is only the end-result of a progressive disturbance of this normal equilibrium, then the problem passes from the strictly medical to the general biological field.

When the study of epidemic disease as a general phenomenon is established on a firmer scientific basis, it may, I think, come to be recognised that the epidemiological Apostolic Succession has passed not through Hippocrates and Sydenham, but through Aristotle and Darwin. I would hazard the guess that the "Origin of Species" will one day be regarded as the most important single contribution to the canon of preventive medicine, and it is interesting to note that the rôle of disease as a selective agent was not ignored by Darwin himself. In his chapter on the Struggle for Existence he writes:

> "When a species, owing to highly favourable circumstances, increases inordinately in numbers in a small tract, epidemics—at least, this seems generally to occur in our game animals—often ensue; and here we have a limiting check independent of the struggle for life. But even some of these so-called epidemics appear to be due to parasitic worms, which have from some cause, possibly in part through facility of diffusion amongst the crowded animals, been disproportionably favoured; and here comes in a sort of struggle between the parasite and its prey."

It will be generally admitted that the more we know of the microbial parasite of any given disease, of its normal distribution in nature, and of its mode of conveyance from host to host, the more successful we are likely to be in snapping some link in the chain of causation which leads up to the epidemic prevalence of the disease in question. It is significant that some of our most striking successes have lain in the field of tropical medicine and in diseases in which an insect vector of infection is involved. Perhaps one of the most perfect examples of the application of biological science to the prevention of disease is afforded by the success which has been attained by stocking stagnant or slowly-moving collections of surface water with top-feeding minnows; which feed on the larvæ; which would develop into the mosquitoes; which would transmit the malarial parasite from host to host.

This is nothing but the application to preventive medicine of Darwin's account of the red clover. As you will remember, it runs:

> "From experiments which I have lately tried I have found that the visits of bees are necessary for the fertilisation of some kinds of clover; but humble-bees alone visit the red clover (*Trifolium pratense*), as other bees cannot reach the nectar. Hence I have very little doubt that if the whole genus of humble-bees became extinct or very rare in England, the heartsease and red clover would become very rare, or wholly disappear. The number of humble-bees in any district depends in a great degree on the number of field mice, which destroy their combs and nests; and Mr. H. Newman, who has long attended to the habits of humble-bees, believes that more than two-thirds of them are thus destroyed all over England. Now the number of mice is largely dependent, as everyone knows, on the number of cats; and Mr. Newman says: 'Near villages and small towns I have found the nests of humble-bees more numerous than elsewhere, which I attribute to the number of cats that destroy the mice.' Hence it is quite credible that the presence of a feline animal in large numbers in a district might determine, through the intervention first of mice and then of bees, the frequency of certain flowers in that district."

The successful prevention of microbial disease has, however, by no means been confined to diseases in which we can eliminate, or reduce to negligible numbers, some insect vector of infection. In my concluding lecture I shall refer briefly to some of the more striking examples, in which an adequate knowledge of the biological factors involved has enabled us to bring about a significant reduction in the ravages of some particular infective disease. All such examples teach the same lesson, the need of a wide biological outlook, if such problems are to be solved. It follows that those methods which have proved their value in general biological research are likely to help us here. Among those methods, both direct experiment and biometry have proved their worth beyond all question. I hope to convince you that the application of a combination of these methods to the study of the spread of epidemic disease promises to yield results of some interest.

It is just seven years since I brought to the notice of this College, in the Goulstonian lectures,[1] some preliminary experiments on the spread of bacterial infection among mice. Since that date I have been largely occupied with experiments designed to yield further information on the same problem.[2-16] It soon became evident that the data derived from such experiments would require analysis by statistical methods far beyond my own capacity, and it was my great good fortune to interest Dr. Major Greenwood in this line of investigation. For the last five years we have worked in close coöperation, and all those experiments, which have seemed likely to yield data of statistical interest, have been jointly planned, and the results jointly considered. As the result of this five years' experience, it has become clear to us that it is only by such close coöperation that results of value are likely to be obtained. It is not enough that the statistician should analyse the results obtained by the bacteriologist. He must take a full share in designing the experiments and in following their course. Similarly, the results of biometrical analysis must be carefully considered in the light of the bacteriological findings, and fresh experiments must be planned to elucidate particular questions which such an analysis has left unanswered.

Many of the results which I wish to lay before you are, therefore, the outcome of a joint investigation,[17] for which Dr. Greenwood and I are equally responsible and which we hope to continue. Many of the issues raised are susceptible of experimental investigation without the aid of statistical methods other than those involved in any biological inquiry. If, from the results of such experiments as we are carrying out, it should be possible to formulate any general description of the spread of epidemic disease, it will clearly be necessary to test the validity of such generalisations by statistical analysis of the data of epidemic diseases as they occur in man and animals under natural conditions, and so to develop the inquiry on its purely biometrical side. At the present moment, we believe that the best hope of elucidating the main questions at issue is to combine the experimental and statistical methods, by developing an experimental biometry of epidemic disease, in which the bacteriological and immunological factors shall not be so complex, and so little susceptible to control, as to defy analysis, while the numerical data shall not be so slight as to preclude the application of statistical methods of inquiry.

In 1922 Flexner,[18] Lynch,[19] Amoss,[20 21] and Webster [22 23] published from the Rockefeller Institute a series of papers recording an independent investigation into epidemics among mice; and from that time onward Webster[24-36] and Pritchett[37-39] have carried out a large series of experiments bearing upon the spread of enteric infection among these animals. Recently, Webster[40-44] has also studied the spread of a respiratory infection in rabbits. During the last few years Neufeld,[45-47] Lange,[48-51] and their co-workers in the Robert Koch Institute in Berlin have investigated many different problems in connexion with the factors which determine natural infection among mice.

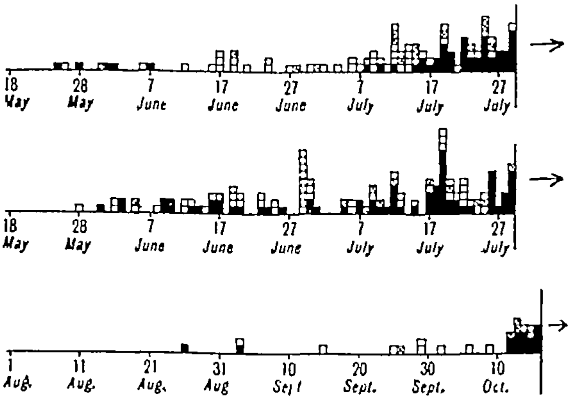
Thus since 1919 there has been accumulated a considerable mass of data bearing on the infection of mice with those bacteria to which they are a natural prey, a problem which is essentially different from the study of the reaction of laboratory animals to bacteria which do not attack them under natural conditions, and which show little tendency to spread from host to host. Many of the experiments recorded, including those which Dr. Greenwood and I have carried out in collaboration, have been specifically designed to investigate the actual spread of epidemic infection among mice, in the hope of obtaining information with regard to the general form of such epidemics under varying conditions. We have hoped in this way to discover certain broad relations, which may later be susceptible of more detailed analysis, by other experiments designed to elucidate isolated problems. Other experiments have been devoted to attempts to solve particular questions with regard to the mechanism of infection with those bacteria which are known to be capable of epidemic spread.

In these lectures I propose briefly to summarise the knowledge which has so far been gained, considering first the data which we have obtained with regard to the general character of such epidemics, and then discussing the factors which may be concerned in producing the observed results.

## THE GENERAL CHARACTERS OF EXPERIMENTAL EPIDEMICS AMONG MICE.

It is unnecessary to refer here to the technical difficulties involved in experiments of this nature, since they have already been considered elsewhere.[4] The only point which need be noted is that all mice which die, and which are not eaten by their companions, are submitted to a full post-mortem examination, including the preparation of cultures from the heart's blood and from the spleen. The unfortunate prevalence of cannibalism among these animals does not allow us to ascertain the cause of every death which occurs, but the majority of the many thousands of mice whose fate has been recorded have been in a condition which has rendered an adequate post-mortem examination possible, and it may safely be asserted that our inability to obtain a complete bacteriological record with regard to every death has not obscured the general course of events. The only two diseases which have so far been studied in any detail are mouse-typhoid and mouse-pasteurellosis, and it is with these alone that we are here concerned.

CHART 1.



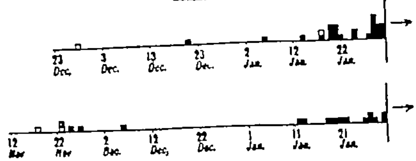
### *The Pre-Epidemic Phase.*

It is logical first to consider those observations which have been made on the initiation of experimental epidemics, but it happens that this part of the problem has, up to the present, received relatively little attention. The great majority of the experiments so far completed have been concerned with the later stages of the epidemic process. The method employed in initiating the spread of infection has differed. In most experiments normal mice have been added to others which have been infected by feeding with the bacterium to be studied; in other cases the infecting mice have been survivors from earlier epidemics. In some experiments a large number of normal mice have been added to their infected fellows in a single batch; in others daily additions have been made, or batches of varying size have been added irregularly.

The records available,[4] inadequate as they are, allow us to form some picture of the different ways in which the specific mortality may be distributed during the pre-epidemic period. The salient points are sufficiently depicted in Charts 1, 2, and 3. In these charts each square corresponds to the death of a single mouse. Where a square is blackened a post-mortem examination established the presence of the particular infection being studied. Where a square is left unshaded such an examination yielded no evidence of this infection, and death was presumably due to some other cause. Where a square is marked with a cross the condition of the dead mouse rendered a post-mortem examination impossible. The arrow to the right of the chart indicates that the epidemic, once established, progressed well beyond the date on which the record ceases.

The three experiments recorded in Chart 1 were concerned with the spread of mouse-typhoid. They were each commenced by feeding a certain number of mice on the causative organism, and thereafter adding normal mice to the cage. In each experiment it is clear that a considerable period may elapse between the occurrence of the first death due to the specific infection and the rise of the first epidemic wave. It will be seen that, during the pre-epidemic phase, there may occur a considerable number of deaths from causes other than the specific infection which is being studied. Such a rise in the mortality from all causes has frequently been noted as a precursor of the main wave of mortality in an experimental epidemic. Whether it has any real significance is a question which has still to be answered.

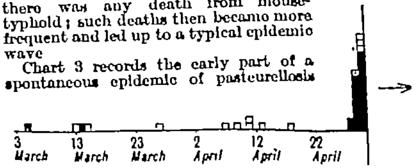
CHART 2.



The two experiments recorded in Chart 2 were initiated by adding to survivors from a previous epidemic of mouse-typhoid four times their number of normal mice, the additions being made in each case as a single batch on the day on which the record begins. In each case it will be noted that a considerable time elapsed before there was any death from mouse-typhoid; such deaths then became more frequent and led up to a typical epidemic wave.

Chart 3 records the early part of a spontaneous epidemic of pasteurellosis which occurred among a batch of some 120 mice, which had been collected in a single cage for another purpose. They had not been intentionally submitted to any risk of infection. It will be noted that a single death from pasteurellosis occurred on March 14th. From then onwards until April 26th a few scattered deaths occurred in the cage, but post-mortem examination of the dead mice revealed no recognisable cause of death. On April 27th two mice died of pasteurellosis, and these deaths were immediately followed by a large wave of mortality from this disease. It may be noted that this spontaneous outbreak of pasteurellosis among our normal stock, which occurred in March, 1921, formed the starting-point of all our experiments on this infection. This disease has never again appeared among our normal animals.

CHART 3.



It is clear from these few experiments that the introduction of infected animals into a normal herd does not suffice immediately to initiate an epidemic of disease, if by an epidemic we mean a wave of morbidity associated with mortality. In these and in all similar experiments our recognition of an epidemic of disease must perforce be based on the observed mortality, since we cannot recognise infection with any certainty in the absence of death.

We must assume that during the pre-epidemic phase some process goes forward which leads to a progressive alteration in the equilibrium between parasite and host, and that it is only when a certain limiting condition has been reached that an epidemic wave of mortality is propagated. In a careful survey of an epidemic of summer diarrhœa Peters [12] observed a sequence of events curiously similar to that recorded in the early stages of these experimental epidemics in mice. He uses the term "epidemic potential" to describe the balance of interacting forces which tends towards the occurrence of an outbreak of disease, and this term appears appropriate and adequate. Employing it, we may assume that the pre-epidemic phase is characterised by a rise in epidemic potential, and that when this has reached some limiting value the next stage of the process, the rising wave of mortality, makes its appearance.

The significance of variations in the form of the pre-epidemic phase, and especially the relation, if any, between the form of this part of the total epidemic process and the form of the subsequent wave of mortality, will be referred to later.

*The Epidemic Phase.*

We may now consider the effect, as judged by the mortality curve, of allowing normal mice to gain access to a cage in which an epidemic is fully established. The first experiment of this kind [3] was concerned with an epidemic of mouse-typhoid, and the results are recorded in Chart 4. On the date when this record commences the epidemic had already been under way for some months, during which the losses by death among the population at risk had been made good by the irregular addition of normal mice. During the greater part of the period covered by the chart normal mice were added at the rate of three a day, irrespective of the number of deaths. During the last 45 days the daily additions were reduced to two animals. On the upper base line are recorded the daily deaths. The lower curve represents the daily cage population. The general character of the progress of mortality is at once obvious. When susceptible mice gain access to the cage at a steady rate the deaths are not uniformly distributed in time, nor do they occur in a purely random fashion. They are grouped in a series of waves, each wave showing minor fluctuations. In Chart 4 there are four such waves, of which the third and fourth are more distinctly separated than are the first and second. These may be followed either on the mortality chart or on the cage-population curve. Successive maxima or minima are separated by periods of between 30 and 10 days. The minor fluctuations in the number of daily deaths are probably of no importance.

It would appear that, when enteric infection is allowed to spread among a herd of mice which is recruited by the addition of susceptibles at a constant rate, some process is set up which waxes and wanes in a more or less regular manner. The equilibrium between parasite and host seems to be a shifting one. As the result of some series of changes, the parasite appears to obtain a temporary mastery; so that a considerable proportion of the mice at risk fall victims to a fatal infection. This is followed by a phase in which there is a decreased tendency for the occurrence of fatal infection, and the death-rate falls. As fresh susceptibles accumulate this succession of events is repeated, and the deaths increase to a fresh maximum, only to fall again when this maximum is passed. The other point to be noted is that there is no evidence that the process has any natural limit in time. This experiment, of which Chart 4 shows a part, was continued over nine months. It was brought to an untimely end by the appearance in the cage of an unrelated infection. Had it been possible to prolong it, there is no reason to suppose that the course of events would have been modified in any essential respect. This point is brought out still more [illegible] in the experiments next to be described.

During the past four years Dr. Greenwood and I have carried out a considerable series of experiments which have enabled us to study this problem in much greater detail.[17] The infection selected for study was mouse-pasteurellosis. A series of epidemics were started, in one case by submitting mice to contact with others which had contracted a spontaneous infection, in others by feeding a number of mice on *Pasteurella muris* and thereafter adding susceptible mice to the cages in which they were housed. In each case the experiment was continued by adding normal mice to the cage at a constant rate, this rate varying in the different experiments. Six such experiments have been performed. The rate of addition and the period of observation in each experiment, up to the autumn of 1924, are shown in Table I. The number given to each experiment corresponds with that recorded in a report which has been published elsewhere.[17]

TABLE I.

| Expt. | No. of mice added daily. | Duration of expt. in months. | Expt. | No. of mice added daily. | Duration of expt. in months. |
|---|---|---|---|---|---|
| 3 | 6 | 8½ | 2*b* | 1 | 17 |
| 2*a* | 3 | 26 | 5 | 1 : 2* | 7½ |
| 4 | 2 | 7½ | 6 | 1 : 3* | 7½ |

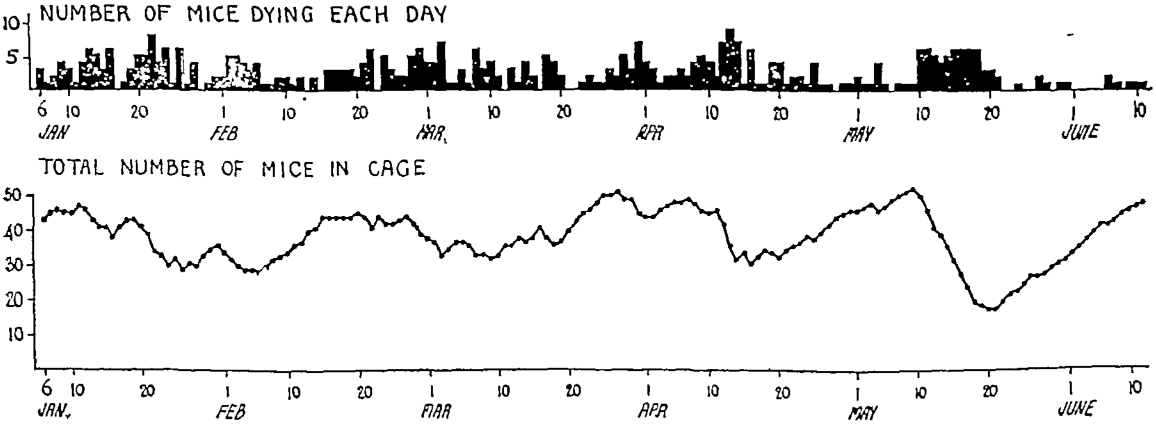
* In Expt. 5 one mouse was added every other day. In Expt. 6 one mouse was added every third day.

In these experiments the progress of mortality has been studied in terms of death-rates, instead of in terms of the actual number of deaths occurring in unit time. In preparing the graphs minor irregularities have to some extent been smoothed out by recording, as the death-rate for any given day, the quotient obtained by dividing the sum of the deaths for the five days of which that day is central by the sum of the cage populations on the same five days. The rate obtained is of the actuarial type—i.e., the probability of dying within the unit of time, the $q_x$ of the life table, instead of the central death-rate, the $m_x$ of most medical publications. There is little difference in the values obtained in this case, but the life-table rate was needed for other purposes and was therefore used throughout. For a full description of the fluctuations in the death-rate reference must be made to our full report. In Chart 5 are recorded the death-rates observed over a five-monthly period in each experiment. The rate recorded is that due to specific mortality. It includes those deaths in which a diagnosis of pasteurellosis was based on a post-mortem examination, followed by the isolation of the causative organism, and those deaths in which cannibalism prevented us from definitely establishing the cause of death. It excludes those deaths in which a post-mortem examination revealed no evidence of pasteurellar infection. We believe that the use of this figure gives us the best approximation to truth at all periods when pasteurellosis is actively spreading in the cage. Almost every dead mouse examined during such periods is found to present the typical lesions of the disease and to yield cultures of *Pasteurella muris* from its tissues. The degree of cannibalism, on the other hand, varies according to the total population of the cage at any moment, according to the particular inclinations of the mice forming that population, and according to the frequency with which the cages are examined and the dead mice removed. In experiments which have to be carried on without interruption over a period of years, it is not possible to examine the cages with equal frequency on each day, so that the degree of cannibalism is subject to random fluctuations. Our records show that the general form of the graphs would not be altered by excluding all deaths, save those in which the diagnosis of pasteurellosis had been definitely established, but the picture presented would certainly depart far more widely from truth than that obtained by the plan which we have followed. One *caveat* must be entered. When few deaths are occurring in a cage, so that the population is steadily increasing, and the appetites of the mice are perhaps whetted by a feeling of general well-being, there is a definitely increased tendency for any mouse which dies to be rapidly devoured by its companions. When, therefore, the death-rate of any herd is very low—as, for example, in the later stages of Experiment 6—the majority of the mice which die over a long period may escape post-mortem examination, and the specific death-rate as above defined may be misleading.

The period of each experiment covered by Chart 5 is selected as giving the best representation of the entire graph for the corresponding epidemic. In the case of Experiments 3, 4, 5, and 6 it covers almost the whole of the actual period of observation up to the end of September, 1924. In Experiments 2*a* and 2*b* it corresponds to periods when fluctuations in the death-rate were well marked. One further point must be noted. The significance of the recorded fluctuations obviously depends on the number of mice on which the rate is based. When the population at risk is small the ratio of the observed death-rate to its probable error may be so low that little significance can be attached to the fluctuations observed. We should pay little attention to small movements in the death-rate, or to the occurrence of irregular or isolated movements when the population at risk is small. The main fluctuations are, however, certainly not due to errors of sampling.

The general character of the progress of mortality in these six epidemics of pasteurellosis is at once obvious from the chart. In Expt. 3, in which six mice were added to the cage each day, the average death-

CHART 4.

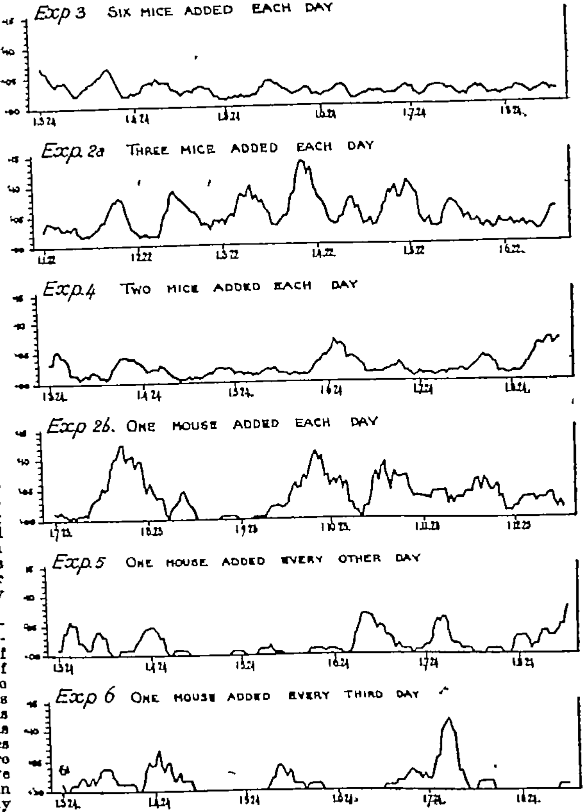


rate is high, but the fluctuations are small. We seem to be approximating to a high but steady death-rate. In Expt. 2*a*, in which three mice were added daily, the average death-rate is also high, higher indeed than in Expt. 3, but the fluctuations are well marked. One wave of mortality follows another without any quiet interval, but they show little tendency to fuse with each other during the period covered by the chart. In Expt. 4, in which two mice were added each day, the average death-rate is lower, but the fluctuations are well marked and distinct. In Expt. 2*b*, in which one mouse was added each day, the average death-rate is lower again, but the waves are very distinct and well separated. In Expt. 5, in which one mouse was added every other day, the average death-rate does not differ appreciably from that observed in Expt. 2*b*, but the waves are very clearly differentiated, and in some instances are separated from one another by quiet intervals during which no death from pasteurellosis occurred. In Expt. 6, in which one mouse was added every third day, the average death-rate is lower again, and the waves of specific mortality are here separated by well-marked quiet intervals, during which the epidemic appeared to have died down completely, only to break out again after an interval. This experiment has now been continued without interruption for over two years and is still in progress. There has occurred during this period a long, quiet interval of over ten months, during which no death from pasteurellosis was recorded; subsequently a further series of waves of specific mortality have been observed.

In Table II. are set out the death-rates recorded in the six experiments, for the whole period of observation up to the end of September, 1924. It will be observed that, with the exceptions of Expt. 2*a* and Expt. 5, there is a steady fall in the death-rate as the rate of addition of susceptibles decreases. In this table there are two additional columns, which give the average daily population in each cage, and the average daily ratio of the number of mice which had lived in the cage for less than 30 days to the number which had been at risk for more than 30 days. It will be noted that there is, except in the case of Expt. 6, a closer correspondence between this ratio and the death-rate than between the death-rate and the average total number of mice at risk. This is particularly striking when we compare Expts. 3 and 2*a*. The ratio of the average numbers at risk is as 155·7 to 63·5, whereas the specific death-rates are as 0·0264 to 0·0366. The herd with an average population two and a half times as large as the other has a lower death-rate. The average under-over 30 ratio, on the other hand, is 2·1 in the herd with the average death-rate of 0·0264, and 2·3 in the herd with the average death-rate of 0·0366. Thus the herd with the higher death-rate, although it has the smaller total number of mice at risk, has a higher average proportion of recent immigrants. (Chart 6.)

It is of some interest to inquire how the course of events will be modified if the addition of normal mice be made irregularly, instead of at a steady rate. In connexion with our investigation of mouse-pasteurellosis we have carried out one such experiment in which we started with 20 infected mice and added 80 normal mice to them on 14/2/24. Another 80 were added on 10/3/24, 50 on 3/5/24, 50 on 11/6/24, and 50 on 1/7/24. Chart 6 shows the sequence of events. The black continuous line records the fluctuations in the specific mortality-rate. The upper broken line shows

CHART 5.



Showing daily death rates in six continued epidemics of mouse pasteurellosis.

TABLE II.

| Expt. | No of mice added per day. | Average daily death rates $q_x$ (specific deaths). | Average daily ratio of numbers under 30 to numbers over 30 days. | Average daily population. |
|---|---|---|---|---|
| 3 | 6 | 0·0264 | 2·1 | 155·7 |
| 2*a* | 3 | 0·0366 | 2·3 | 63·5 |
| 4 | 2 | 0·0244 | 1·6 | 60·6 |
| 2*b* | 1 | 0·0184 | 0·97 | 40·8 |
| 5 | 1 : 2 | 0·0190 | 1·2 | 20·2 |
| 6 | 1 : 3 | 0·0124 | 1·0 | 16·2 |

the variation in the cage population, and indicates the points at which additions were made. It will be seen that the first addition was followed by a large initial wave of mortality, which is two-peaked, and which had almost subsided when the second addition was made on 19/3/24. This addition had very little effect on the rate of mortality, which remained at a low level and had fallen to zero when the third addition was made on 3/5/24. This addition was followed by a slow and slight rise in the death-rate, which shows three fluctuations before the next addition was made on 11/6/24. This addition was made shortly after the small wave of mortality which began on 1/6/24 had passed its crest. It was followed by a very definite rise in the death-rate, leading to a wave which had passed its crest and fallen almost to zero when the final addition of normal mice was made on 1/7/24. This addition was almost without effect on the death-rate.

CHART 6.

Pasteurellosis

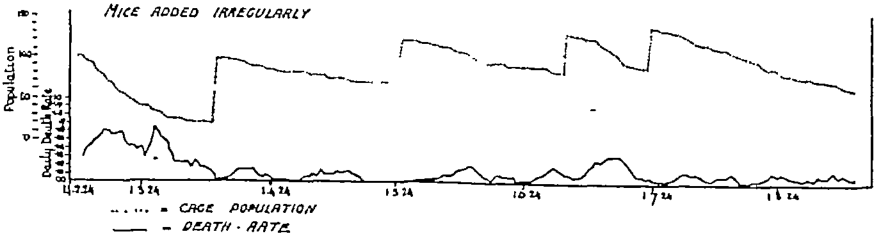


CHART 7.

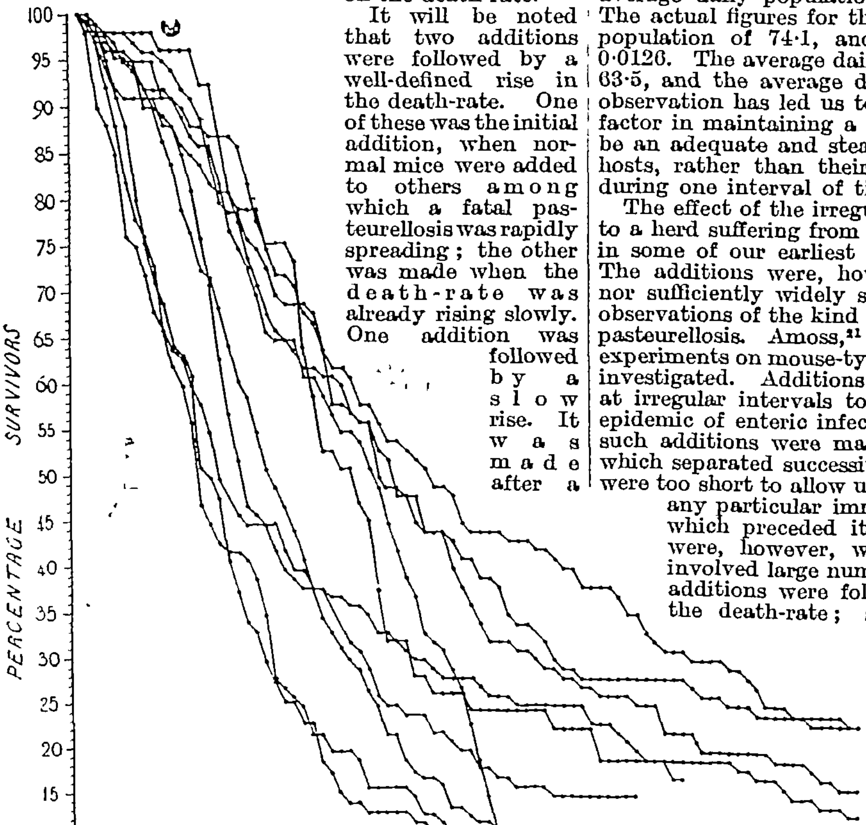


Showing daily percentage of survivors in ten epidemics of mouse typhoid.

It will be noted that two additions were followed by a well-defined rise in the death-rate. One of these was the initial addition, when normal mice were added to others among which a fatal pasteurellosis was rapidly spreading; the other was made when the death-rate was already rising slowly. One addition was followed by a slow rise. It was made after a long interval had elapsed since the first large wave, during which a low death-rate had prevailed. Two additions were followed by no significant rise in the death-rate. Each was made immediately after the subsidence of a considerable wave of mortality. It would be unwise to stress in any way this relation between the phase of the epidemic at which an addition is made and its effect on the subsequent death-rate. Far more thorough investigation will be needed before we can arrive at any just conclusion on this point. We may, however, note that the immigration into an infected herd of relatively large numbers of normal animals, in a single batch, may sometimes be followed by a considerable rise in mortality, and at others may have little apparent effect. It may also be noted, and this is a point of some interest, that the average specific death-rate among this herd was the lowest but one observed in this series of experiments, while the average daily population was the highest but one. The actual figures for this epidemic gave an average population of 74·1, and an average death-rate of 0·0126. The average daily population in Expt. 2*a* was 63·5, and the average death-rate was 0·0366. This observation has led us to suggest that the important factor in maintaining a high epidemic potential may be an adequate and steady circulation of susceptible hosts, rather than their presence in large numbers during one interval of time.

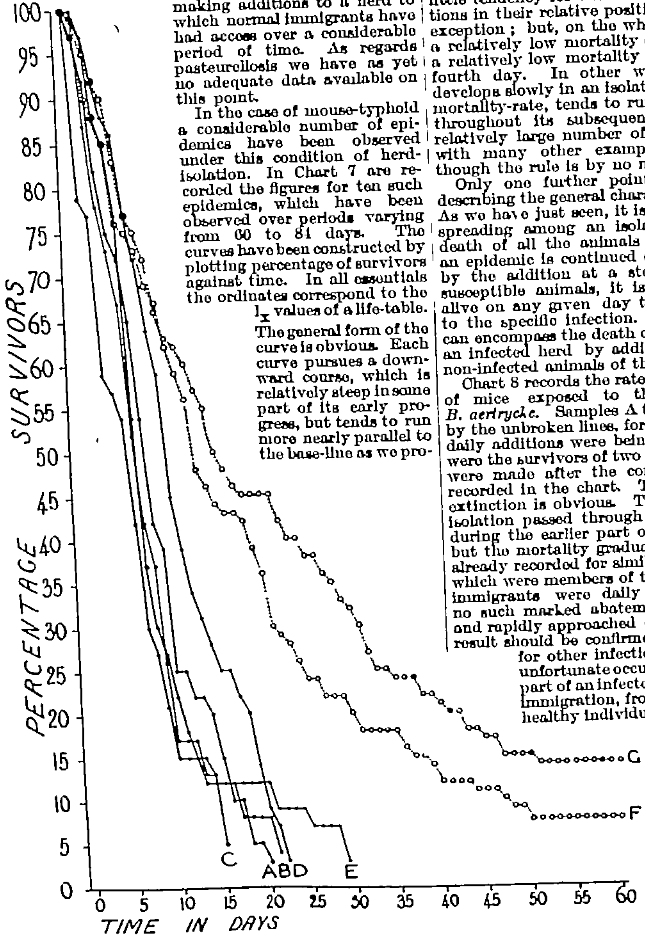
The effect of the irregular addition of healthy mice to a herd suffering from enteric infection was studied in some of our earliest experiments on this disease. The additions were, however, neither large enough nor sufficiently widely spaced, to allow us to make observations of the kind recorded above in the case of pasteurellosis. Amoss,[11] in 1922, recorded a series of experiments on mouse-typhoid in which this point was investigated. Additions of normal mice were made at irregular intervals to a community in which an epidemic of enteric infection was spreading. Twelve such additions were made, but six of the intervals which separated successive additions from each other were too short to allow us to differentiate the effect of any particular immigration from that of those which preceded it. The remaining additions were, however, well separated in time and involved large numbers of mice. Some of these additions were followed by a marked rise in the death-rate; some were almost without effect. The results recorded by Amoss for mouse-typhoid are thus very similar to those which we have observed in pasteurellosis. There is, however, a difference in technique, which may have introduced a disturbing factor. In our experiments all mice at risk were housed in a single cage, thus ensuring as uniform an admixture as possible of the individuals within the experimental herd. In Amoss's experiments the mice were housed in a large number of small cages, and infection was spread from cage to cage by the activities of the attendant during the routine process of cleaning and feeding. Opportunities for random variations may therefore have intervened in these epidemics which were absent from our own experiments; but the general course of events, over the long period covered by Amoss's investigation, does not suggest that the fluctuations in mortality were due in any large part to variations in the effectiveness of the carriage of infection from cage to cage.

There remains for consideration the sequence of events, observed when an epidemic is allowed to spread among a herd of mice without any additions, beyond the initial mixture of infected and susceptible animals, or when we cease making additions to a herd to which normal immigrants have had access over a considerable period of time. As regards pasteurellosis we have as yet no adequate data available on this point.

In the case of mouse-typhoid a considerable number of epidemics have been observed under this condition of herd-isolation. In Chart 7 are recorded the figures for ten such epidemics, which have been observed over periods varying from 60 to 84 days. The curves have been constructed by plotting percentage of survivors against time. In all essentials the ordinates correspond to the $l_x$ values of a life-table.

The general form of the curve is obvious. Each curve pursues a downward course, which is relatively steep in some part of its early progress, but tends to run more nearly parallel to the base-line as we proceed further to the right. In all cases deaths have become relatively infrequent by the sixtieth day, and have almost ceased to occur at the end of three months. In all cases a certain proportion of mice are left alive on the day when the experiment terminates, the percentage of survivors varying, in the experiments here recorded, between 6 and 33 per cent. There is no reason to suppose that, had these experiments been further continued, any appreciable increase in the total specific mortality would have been noted.

CHART 8.



It would appear that an epidemic of mouse-typhoid which is allowed to run its course among a herd of mice kept in isolation will result in a total mortality varying between 65 and 95 per cent., but will seldom or never lead to the complete extermination of the herd.

There is another point in connexion with this series of curves to which we would draw attention. It will be noted that, after about the thirtieth day there is little tendency for the curves to show marked alterations in their relative position. There is one striking exception; but, on the whole, the herd which shows a relatively low mortality on the thirtieth day shows a relatively low mortality on the sixtieth or eighty-fourth day. In other words, an epidemic which develops slowly in an isolated herd, as judged by the mortality-rate, tends to run a relatively mild course throughout its subsequent stages, and to leave a relatively large number of survivors. We have met with many other examples of this phenomenon, though the rule is by no means an invariable one.

Only one further point need be referred to in describing the general characters of these experiments. As we have just seen, it is unusual for any epidemic, spreading among an isolated herd, to lead to the death of all the animals at risk. When, however, an epidemic is continued over a long period of time, by the addition at a steady or irregular rate of susceptible animals, it is found that all the mice alive on any given day tend ultimately to succumb to the specific infection. It would appear that we can encompass the death of certain individuals among an infected herd by adding to the herd normal and non-infected animals of the same species.

Chart 8 records the rate of extinction of six samples of mice exposed to the risk of infection with *B. aertrycke*. Samples A to E, whose fate is recorded by the unbroken lines, formed part of a herd to which daily additions were being made. Samples F and G were the survivors of two herds, to which no additions were made after the commencement of the period recorded in the chart. The difference in the rate of extinction is obvious. The mice which were kept in isolation passed through a period of high mortality during the earlier part of the period of observation, but the mortality gradually subsided in the manner already recorded for similar isolated herds. The mice which were members of the herd to which susceptible immigrants were daily gaining admission enjoyed no such marked abatement of their risk of death, and rapidly approached complete extinction. If this result should be confirmed in future experiments and for other infections, it would appear to be an unfortunate occurrence for individuals forming part of an infected herd to be subjected to the immigration, from without that herd, of other healthy individuals of their own species.

## CONCLUSIONS.

The following conclusions seem to be justified by the evidence which has been summarised above.

In experiments in which the environmental conditions are kept relatively constant, in which meteorological variations can apparently play little part, and in which the food-supply is adequate in amount and constant in its general character, the admixture of healthy and infected mice is followed by the epidemic spread of those bacterial diseases which have been studied.

The initial mixture of infected with susceptible hosts is followed by a pre-epidemic phase of variable duration, in which infection is certainly spreading among the population at risk and may cause the death of some individuals within the herd, but during which the epidemic potential has not attained a level which will result in a well-marked wave of mortality.

When the pre-epidemic stage has been passed and a definite epidemic prevalence of the disease has been established, the further course of events is largely determined by the rate of immigration of susceptible hosts. If no such immigration occur the epidemic gradually dies down, leaving a varying number of survivors.

If susceptible animals be added regularly to the herd the form of the fluctuations in the resulting death-rate and its average value are mainly determined by the rate of immigration. With a moderate immigration rate the deaths tend to occur in a series of well-marked waves without any quiet interval. If the rate of immigration be diminished the waves of mortality tend to be more widely separated from each other, the intervening quiet intervals sometimes lasting over several months. If the rate of immigration be increased successive waves of mortality tend to become fused together. The average death-rate may not be so high as that observed at the peak of a wave of mortality during an epidemic in which the immigration-rate is much lower, but the fusion of the waves results in a high and relatively steady death-rate.

If irregular additions be made, the effect of such additions on the subsequent death-rate may vary widely. It would seem that the effect of any one addition is largely determined by the equilibrium between parasites and hosts which exists at the time when that addition is made. The irregular addition of large batches of susceptible animals appears to result in a lower average death-rate than that which follows the frequent and regular addition of smaller batches, even though the average population at risk be larger in the former case than in the later. There is a suggestion that a steady circulation of susceptibles is a more important factor in favouring the epidemic spread of disease than is the total number of mice exposed to risk.

There is some evidence to suggest that an epidemic, which spreads slowly among an isolated herd during its earlier stages, will lead to a smaller total mortality than will another epidemic of the same disease, which spreads rapidly within a short time of its initiation. There is also evidence to suggest that a herd among which an epidemic is spreading will approach extinction more rapidly if it be subjected to the immigration of susceptibles of the same species than if it be kept in isolation.

A bacterial infection which tends to spread naturally from mouse to mouse under the conditions of these experiments may be maintained in an experimental herd for an indefinite period of time, on the sole condition that the herd be replenished by the immigration of susceptible animals, even though the rate of immigration be very slow. In general it would appear that the movement of susceptible but uninfected individuals is one of the main factors in determining the course and duration of the epidemic spread of bacterial disease.

# Lettsomian Lecture

ON THE

## PRINCIPLES OF TREATMENT IN RELATION TO DISEASES OF THE NERVOUS SYSTEM.

*Being the Second Lettsomian Lecture[*] in 1926, delivered before the Medical Society of London on Feb. 24th,*

By E. FARQUHAR BUZZARD, M.D. Oxf.,
F.R.C.P. Lond.,
PHYSICIAN TO ST. THOMAS'S HOSPITAL.

I AM not infrequently told that neurological practice must be very disheartening, as there is little or nothing to be done for organic diseases of the nervous system. This indictment holds equally true for all other branches of medical practice, if we lay no claim to be healers or if we appraise impartially and ungrudgingly the silent influence continually exerted by Nature against the forces of disease and refrain from over-calling any share we may have in the success of our combined efforts. Not the least difficult of our responsibilities is that of weighing the results of treatment, of eliminating from our minds the post hoc, propter hoc process of reasoning and of reviewing all obvious and isolated conclusions in the light of accumulated experience.

From a physiological point of view neurology is distinguished from other specialties in that the organs with which it is concerned are endowed with a number of dominating functions in the absence or failure of which those of all other organs, however healthily preserved, are of little value. Speaking anatomically, the brain and spinal cord, at any rate in the majority of instances, differ from most other organs in possessing little or no superfluous material. These are two considerations which impose, or should impose, on the surgeon a degree of restraint he is unaccustomed to feel when invading other less particular territories of the human frame.

It is, perhaps, unseemly for a physician to discuss in public the terms upon which his surgical brother should be invited to his assistance, but, in order to forestall reproach, I will preface the remarks I propose to make on the indications for surgical intervention in cases of intracranial tumour by stating at once that my respect for brain surgery has been steadily growing for many years. We should be thankful that the risks and responsibilities it involves and the frequent disappointments with which it must necessarily be associated have not deterred its exponents nor checked its scientific progress. It is, perhaps, impossible for anyone to rate the value of surgical intervention in relation to tumours of the brain who has not seen and followed a large number of cases. There must be many medical men whose small personal experience in this direction can only have led to pessimism, just as there may be others with equally meagre, but more fortunate, experience who have become unduly optimistic. Without being in a position to offer you statistical proof for the opinion, I hold the view that the results obtained from surgical intervention are far more satisfactory than they were 20 years ago, and that credit for this can be allotted not solely to advances in surgical skill, judgment, and technique, but also to the fact that the diagnosis is, on the whole, made earlier and more accurately than it used to be.

---

[*] The first lecture appeared in The Lancet, Feb. 20th, p. 377.

The subject under discussion is one in which principles of treatment are so intimately involved in the question of diagnosis that I must ask to be excused if I appear to wander a little way from the title of these lectures.

### SURGICAL INTERVENTION IN TUMOURS OF THE BRAIN.

The problem most commonly presented to us is of the following nature. The conclusion has been arrived at that a patient's symptoms are due to the presence of a tumour involving a part of one cerebral hemisphere or one lobe of the cerebellum. Although confident about its localisation we are unable to form any exact opinion as to its nature. We have applied such tests as seem necessary to put a gumma out of court, and we find no evidence to suggest that the cause of trouble is a secondary neoplasm. Examination of the blood and cerebro-spinal fluid as well as the history of the patient do not favour, although they cannot absolutely negative, the possibility of an abscess or a tuberculoma, and radiology has failed to throw any light on the question. The nature of the lesion can now only be ascertained by inspection through an opening in the skull, and upon what is found at the operation depends the answer to the question whether permanent or only temporary relief of symptoms can be afforded. If there is a menace to vision in the shape of papilloedema or if headache and vomiting have been prominent symptoms, almost certain relief can be promised, but beyond that it is wise to refrain from prophecy.

At this stage I would lay emphasis on the fact that intracranial exploration is a field of surgery which is rich in surprises. When everything has seemed to point to the presence of an infiltrating glioma with its attendant bad prognosis, we may find an endothelioma or chronic abscess capable of complete removal, or vice versa. But there is another point to which I would draw special attention and which has not, perhaps, attracted the notice it deserves in this connexion. The most promising group of cases of intracranial tumour, from the point of view of permanent relief afforded by operation, is that in which headache, vomiting, and optic neuritis are symptoms conspicuous by their absence. In spite of the fact that we have all been taught to regard these as the cardinal symptoms of intracranial tumour, we must look to cases without them for providing perhaps the majority of examples of successful treatment. This is not merely a question of early diagnosis, although it means much to the surgeon that his services should be called upon before intracranial tension is much raised. It is due to the fact that slow growing endotheliomata may reach a very large size without provoking the cardinal symptoms and that they can often be entirely removed with little fear of any recurrence. Two instances illustrating this axiom and presenting slight but important differences in their clinical histories may be worth a brief description.

### *Clinical Cases.*

CASE 1.—On June 8th, 1918, a young man, about 25 years of age and apparently in perfect health, was out riding when he felt his eyes being forced involuntarily to his left side. This passed off in a few seconds, but later in the day the same thing recurred, followed by forcible turning of the head to the left and some twitching of the left side of the face and loss of consciousness. Fits, resembling either the first or second of those I have described, were repeated at intervals up to the time when he came under my observation early in December of that year, but in between the attacks he was well and the only headache he experienced was after a severe fit.

I had many opportunities of examining the patient in the course of the next six weeks, and during the whole of that time there were no physical signs, in particular no optic neuritis, no headache, and no vomiting. At the end of the first week in January, 1919, I noticed slight weakness of the left face and a diminished abdominal reflex on the same side. On Jan. 12th Mr. P. W. G. Sargent operated at my request, turned down a large osteo-plastic flap in the right frontal region, and removed an encapsuled hard tumour about the size of a hen's egg, evidently growing from the under surface of the dura mater and embedded in, although easily detached from, the frontal lobe.

The patient recovered rapidly and perfectly from the operation, was prescribed some bromide to take regularly, and had three fits in the course of the next 12 months. These attacks continued to recur at long intervals, but when I heard from the patient at the end of December, 1925, he had been free from fits since August, 1924, and had been leading an active and busy life for several years.

CASE 2.—On Oct. 1st, 1924, I was consulted by a man, 52 years of age, who had always led a very active life and who, in 1902, had sustained two somewhat severe falls from horseback, resulting in slight concussion but no serious after-effects. In 1923 he first noticed a tendency to bump into objects on his left side and took medical advice with the result that his Wassermann reaction was tested and proved negative. In April, 1924, he noticed some failure of his left leg when salmon fishing, and that his left hand was becoming clumsy. He did not complain of headache, although he admitted that a severe physical strain would sometimes provoke a slight pain in his head. He was convinced that an exostosis in connexion with his seventh cervical vertebra, which had been revealed by an X ray photograph of his spine, was the source of his disabilities.

On examination he proved to have complete left hemianopia, a slight loss of postural sensibility and tactile discrimination in his left hand, a diminished left abdominal reflex, and an extensor response on stimulating the sole of his left foot. There was no optic neuritis but a slight though definite slowness of cerebration and perhaps some mental confusion.

A very good X ray photograph, taken by Dr. Shires, revealed a slight thickening of the bone in the right parieto-occipital region. On Oct. 22nd, 1924, Mr. Sargent removed an endothelioma as large as a man's fist from the surface of the brain in the right parieto-occipital region, with the result that three months later he appeared to be perfectly well, able to lead a fairly active life, and to have regained practically the whole of his left visual field. When I saw him a year after his operation he was able to enjoy a stiff day's partridge shooting and to do his share of ornithological execution.

A number of interesting questions are raised by a consideration of these two stories. Among those which cannot be discussed now are (*a*) why did the first patient suffer from fits and why did the second present complete freedom from that symptom, and (*b*) what is the relationship of injury to the development of neoplasm? There was no history of head injury in the first case, and a history of two fairly severe blows on the head in the second case occurring 20 years before any symptoms of an intracranial tumour were manifested. On the other hand, the records of these two patients do illustrate the importance of attaching no weight to the absence of headache, vomiting, and optic neuritis when surgical intervention is being considered in relation to intracranial tumours. Further, I would urge that the administration of bromide should always be prescribed after such operations, and that it should be continued for a few months even when there is no history of fits either before or after the removal of the tumour, and for many years in those cases in which fits have been a prominent feature. Finally, I would draw attention to the complete recovery of the left visual field in the second patient after treatment in spite of the fact that it must have been greatly encroached upon for a period of at least two years.

May I, in the next place, drive home the principle that intracranial surgery is full of surprises and, by way of illustration, cite a case in which I certainly neglected it.

CASE 3.—About a year ago a boy, 11 years of age, was brought to me with a history of having suffered for three months from early morning headaches, accompanied by occasional vomiting, and from persistent diplopia. On examination he was found to hold his head inclined to his left shoulder, to have papilloedema in both eyes with rather more swelling in the left, coarse nystagmus more marked on looking to the right, weakness of the right superior oblique muscle, perhaps a little ataxy affecting the left leg more than the right, and a diminished left abdominal reflex. These symptoms and physical signs pointed without doubt to raised intracranial pressure due to the presence of some foreign substance in the posterior fossa. There was a strong family history of tubercle on the mother's side and a brother of the patient had recently died from tuberculous meningitis. Notwithstanding the absence of pyrexia and of any abnormal constituent in the cerebro-spinal fluid, I came to the conclusion that the law of probability favoured the diagnosis of a cerebellar tuberculoma, and I advised prolonged and complete rest with as much good food and fresh air as were obtainable. For this purpose he was admitted under my care into St. Thomas's Hospital. Headache and vomiting became gradually less severe and less frequent, but the optic neuritis and other ocular signs persisted. After watching him carefully for nine months and finding no improvement in the condition of the optic discs, I decided to ask Mr. Sargent to decompress the posterior fossa, still believing that a tuberculoma, perhaps inactive and encapsuled, would be found. As it turned out there was discovered a simple but large meningeal cyst, the evacuation of which has completely relieved the patient of his symptoms and has led to the disappearance of his papilloedema. The operation might have been carried out nine months earlier with equally good results if the principle of looking at the brain before finally deciding on its nature had been followed.

In this particular instance there seemed to be some justification for the course I adopted, and I might still be inclined to do the same under similar circumstances. Possibly I may, in future, exercise my patience for a somewhat shorter period of time before seeking the help of my surgical colleague. At the same time, having the patient under almost daily observation, I was able to watch the optic discs and to ask for the relief of pressure before any atrophic changes supervened on the neuritis, thus eliminating any risk of the visual acuity becoming permanently damaged.

From what has been said already, you will gather that I do not regard the localisation of intracranial lesions as a difficult task compared to that of determining their nature, and that one of the most important indications for surgical intervention is in many cases the necessity for seeing and feeling the tumour. If, on the other hand, the tumour is so placed that its removal is out of the question, there is no need to ascertain its nature by exploration, although a decompression may be indicated for the purpose of relieving suffering. The latter operation should be avoided if relief can be afforded by other measures, as the prolongation of life associated with a cerebral hernia of gradually increasing dimensions is an experience which is undesirable in the interest of the patient and of his family. It is hardly necessary to add that once an operation has been decided on, delay in carrying it out may be attended with grave risk when headache and vomiting are severe or when the patient's pulse is becoming slow or his respiration disturbed in rate or rhythm. Sudden death a few hours before a contemplated operation is an occurrence which is not as uncommon as it is avoidable.

### THE TREATMENT OF EPILEPSY.

We must sadly admit that the last quarter of a century, although not devoid of praiseworthy efforts, has seen little light thrown on the pathogenesis of epilepsy, and has supplied us with no substantial reasons for altering what may be termed its traditional treatment. Were it not, indeed, that certain principles of treatment, in my opinion of considerable value, are frequently overlooked or neglected, I should have been tempted to omit their consideration from these lectures.

Before embarking on a task already sufficiently invested with gloom by its note of introduction, let me allay some of your fears by expressing at once my intention of confining my remarks to the principles governing the treatment of epilepsy in its earliest stages and avoiding those which are concerned with the care of patients suffering from the disorder in its established form.

In order to lay down principles governing the treatment of any disorder it is desirable to accept, even if only provisionally, some theory, however vague, which appears to offer an explanation of its origin and qualities. In regard to epilepsy, which I describe purposely as a disorder rather than a disease, I propose to accept the view that it is a manifestation of instability on the part of some important nervous mechanism closely allied to, if not identical with, the vasomotor system. In other words, I regard epileptic attacks, slight or severe, as only the occasional outward and visible signs of some permanent underlying nervous state which is inherent in a certain proportion of the population. I would go, perhaps, further and submit that we are all epileptic in the sense that under entirely favourable circumstances and to sufficient provocation even the most stable of us might respond in an epileptic manner. If we exclude individuals whose personalities have been altered in the course of years as the result of constantly recurring fits and of all their psychological consequences, and also the mental defectives among whom epileptic phenomena are common, and pay attention only to children who have had but a few attacks, it is impossible to say that the majority of them are very different from their companions in the intervals between their attacks. At any rate, they are rarely recognised as being in any way exceptional, either by parents or medical attendants, until the occurrence of one or more fits gives them their distinctive mark. While it is true that psychological investigations have seemed to show that the minds of most epileptics approximate to a certain type, workers in this field of research do not suggest that the type of mind is confined to epileptics, nor do they attempt to explain why only a proportion of persons possessing it are subject to fits. Again, we are aware that out of a hundred persons who suffer from head injuries of moderate severity, a small number will subsequently develop epilepsy, but we should find it very difficult to identify that small number beforehand, or to point out the characteristics which distinguish them from their fellows afterwards.

There are many other similar considerations bearing on the nature of epilepsy, all of them deserving careful study, but as I am concerned for the moment with those which may throw light on principles of treatment, I will refer briefly only to two or three. It is a matter of common knowledge that the onset of several acute specific fevers is not infrequently associated with epileptic attacks in children, very rarely in adults, and that such children may never manifest any epileptic tendencies at any other times. Again, the occurrence of attacks only during dentition or during a short period of time about the age of puberty is within the personal knowledge of most of us. Finally, we have to remember a small group of individuals who, apparently normal in every other respect and often leading very active and useful lives, are subject to occasional epileptic attacks at long intervals and who may be described as none the worse for them.

If, with such information at the back of our minds, we accept the view that epileptic attacks are only manifestations of a permanent degree of instability on the part of some nervous mechanism, if we agree that this instability is usually exaggerated by repeated attacks, and if we do not deny that in a small proportion of cases treatment meets with success, it is clear that early diagnosis of the disorder and the frank recognition that a cessation in the occurrence of attacks does not in any way constitute a cure or justify the neglect of whatever successful measures may be in force, are two of our most important therapeutic necessities. This belief has, in my case, received much encouragement from experience, in that most of the cases met with in private or hospital practice which have responded to treatment have been diagnosed at a very early stage and have persevered with treatment for long periods of time.

### "*Embryonic*" *Signs as an Aid to Early Diagnosis.*

Early diagnosis of epileptic instability before any of its manifestations have appeared on the scene is an deal which in the present state of our knowledge seems almost out of reach, but the next best thing would be a more general recognition of its most trivial "embryonic" signs. Common among these are so-called regional jerks which precede other epileptic phenomena by many months and sometimes by years. They may be best described as identical with the involuntary sudden jerk of a limb which most people have experienced at some time or another when in the twilight of sleep. They occur frequently at that time and still more frequently in the morning either before the patient leaves his bed or while he is dressing. So violent may they be that articles in his hand may be flung to the other end of the room or, if a leg is involved, a fall to the ground may result.

Another early manifestation is a form of aura without its subsequent developments. This is often subjective, in that only the patient can describe it and he sometimes fails. There is some momentary interruption in the continuity of his mental processes associated perhaps with some local sensory disturbance, a smell, a vision, a feeling of tingling, or just what the patient may call a "wave of unreality." Such auræ are not accompanied by any lapse of consciousness, a feature of its next development, the petit mal attack. It is to be noted that these trivial epileptic phenomena resemble the more mature forms in their partiality for occurring in the borderland between sleep and full awakedness, a time when we may assume that the circulation in the higher nervous centres is in an unstable state of transition.

But these phenomena are not trivial if their true significance is appreciated and they should all be assessed as manifestations of the epileptic state, as characteristic as a major attack. A history of such embryonic signs preceding the first convulsion can often be obtained from patients who come for advice and it is rarely found that they have been regarded seriously. If treatment were more commonly initiated with their appearance, I am convinced that we should meet with more success.

But there are other stories relating to the development of epilepsy to which, on account of their frequency, reference must be made. A child, apparently healthy and about 12 or 13 years of age, has a major epileptic attack. Ingenuity is exercised in finding a satisfactory explanation and the word "epilepsy" is not even whispered. The excitement of an evening spent at the "pictures" or an unusually hearty meal suffice as plausible excuses for the patient's lapse from grace. Perhaps a bottle of a bromide mixture is prescribed and duly drunk, and then life is resumed as if nothing had happened. Six months later the second fit occurs and perhaps the blame for it is again satisfactorily apportioned. Three months elapse before the third fit comes along and treatment is commenced, nine months too late. A variation of this tale is supplied by the patient who is treated with bromide for six months after the first attack; the medicine is then cut off and the second fit occurs within the next few months.

I should like to lay down the principle that any manifestation of epilepsy in childhood should insure treatment being persevered with until adult life has been reached, however successful it may have been in preventing any repetition of the first sign. Even then the cessation of treatment should be carried out very gradually and with caution. A dog is allowed one bite before appropriate treatment is carried out; a child should not be allowed to exhibit any manifestation of epilepsy without the immediate initiation of proper therapeutic measures.

### *Individual Treatment.*

We have next to consider the treatment which must take into account the inherent and, perhaps, permanent instability as well as its various forms of expression. To deal with the latter first, each case must be studied as a separate problem. What have appeared to be the exciting causes, emotional disturbances, fatigue, bad atmospheres, indiscretions in diet, and so on? Measures for their avoidance must, if possible, be taken. But in laying down any restrictions with this object in view we should be strongly influenced by a desire to make the child's life as little different from that of his fellows as possible, and so to prevent the inevitable psychological effects which accompany the consciousness of such an unenviable distinction. In this connexion I would earnestly deprecate the not uncommon practice of interfering with a child's education on the plea that his brain must be relieved from all strain. While agreeing that his or her work should be carefully regulated and the conditions, physical and psychological, under which it is done critically reviewed, I have never been able to satisfy myself that the occupation provided by lessons is anything but beneficial. The same remark applies with equal force to games, so long as they are wisely supervised. It is much more likely that fault can be found with the psychological atmosphere of a school than with its work or play.

In the next place, brief reference is due to those physical sources of irritation which loom so large in the eyes of the public, and sometimes of the profession, as agencies of disease. Septic tonsils, adenoids, errors of refraction, worms, and vulvitis no doubt may play a part as exciting causes, but their correction does not relieve the doctor of his responsibility for dealing with the underlying instability without which no manifestation of epilepsy would have made its appearance.

Finally, we must turn to the medicinal measures which are at our disposal and which, in my opinion, are the only ones which exert an influence on the essential disorder of nervous function. Here we are faced by very real difficulties based on the profound prejudice with which the use of the bromide salts is regarded, chiefly, but not solely, by the lay mind. This prejudice might appear extraordinary to many of us, did we not recognise that it has grown from the misuse rather than from the use of our most valuable remedy. That it has been tried in large numbers of cases without success and that it has appeared to do harm in many others are sufficient grounds for its discredit. Nevertheless, allowing for individual idiosyncrasies which must necessarily influence our use of any drug, the bromides have been convicted, through no fault of their own, of many crimes of which they are not really guilty. Given irregularly, or for too short a time, they are blamed for lack of success. Given in too large or too frequent doses they are responsible for toxic states which are inevitable. Given in appropriate doses without success, a result which must often ensue, especially when their use has been too long delayed, the depression really attendant on their failure to cure is laid at their door.

### *The Use of Bromides.*

It is when we review our successes that we find the evidence requisite for a belief in the beneficence of bromides and in the factors essential for their favourable action. Let me summarise briefly the principles which should govern their use. (1) They should be prescribed as soon as any manifestation of epilepsy makes its appearance, irrespective of any excuses which may be manufactured for the latter.

(2) The dose should be the minimum required for its purpose, a matter requiring general as well as particular experience. (3) The number of doses in 24 hours should be as small as possible, and should be timed in accordance with any special features of the case under consideration. In nocturnal epilepsy, for instance, a dose at bedtime is often all that is required; in other instances a dose half an hour before leaving bed in the morning is desirable. (4) The administration must be regular and continued for an indefinite time according to age and other circumstances, certainly not according to any rule of thumb such as one, two, or three years. (5) A small quantity of arsenic, 2 or 3 minims of Fowler's solution per dose, should always be given with the bromide.

If these principles were more universally observed, I am convinced that the percentage of cases of epilepsy successfully treated would be greatly increased, and that the popular notion in regard to bromide exerting a depressing influence on the mental activity of patients would disappear. It has been my experience, not once but many times, to hear from patients that they are happier and brighter as the result of taking bromide, an opinion heartily endorsed by those with whom they are in daily contact. I believe that bromides exercise a specific stabilising influence on some nervous mechanism apart from any effect that they may have on general reflex excitability.

While pinning my faith to bromides, I am not insensible to the value of other drugs as adjuvants, and there is no doubt that luminal has proved useful, sometimes alone, but more often in combination with bromide. It is a drug, however, which some patients cannot tolerate at all and which others cannot continue to take as long as is desirable without ill-effects. Borax, belladonna, and digitalis may be added to bromide mixtures, sometimes with advantage, but it is difficult to lay down any indications for their employment, and a long experience of the first-named does not permit me to share the optimistic views which have been expressed concerning its value.

Although introducing the subject of epilepsy in sufficiently gloomy terms, you may have been led by subsequent remarks on the use of bromides to regard me as a fanatical optimist obsessed with the idea that a sufficient ingestion of these salts would suffice to rid us of one of the greatest scourges of the human race. Unfortunately, I hold no such faith, realising, as one must, that a large proportion of our epileptic patients are more or less degenerate before they are obviously epileptic and that no method of treatment, even if successful in eliminating fits, would make of them efficient citizens. But it is time that something was said to combat the unjustifiable prejudice which prevails in many quarters against our most powerful weapon in the treatment of epilepsy. Greater moral courage is required of us in two directions; first of all, the courage to recognise and frankly confess the first evidences of epilepsy; and secondly, the courage to insist, in spite of all opposition, on the importance of immediate and long-continued treatment on the lines I have indicated. Epilepsy is a form of disorder which must be firmly suppressed without delay, and kept in subjection by fearless and unrelenting vigilance over a period of time which admits of no definition.

### Syphilis of the Nervous System.

In the course of my first lecture I ventured to submit that as physicians we should never claim to cure disease. May I now go a step further and submit that syphilis of the nervous system would be practically unknown if we did not claim to cure syphilis. That statement is not strictly accurate because there are always a number of persons who become infected with syphilis, who are either unaware of the fact or who neglect to be treated, and who may at any time develop syphilitic lesions of the nervous system. But with these exceptions the patients who present themselves to us with tabes dorsalis, general paralysis of the insane, cerebral syphilis, syphilitic my
&c., have mostly been sacrificed to the time-hon
but groundless tradition that a medical man pos
the knowledge which justifies him in telling a p
that he has been cured of syphilis. It is tru
large numbers of patients suffering from syphil
cured, and it is probably equally true that mo
cured now than used to be 20 years ago, but th
remains that we have no means of deciding i
particular case whether or not a cure has
effected. Twenty years ago we used to see pa
suffering from tabes dorsalis who had been "c
of syphilis by means of courses of mercury l
from two to five years, according to the pe
predilections of the curer. Now we are cons
meeting with similar sufferers who have been "c
by drastic courses of arsenical compounds, in ad
to or without mercury.

The public have always asked for cures a
deference to their wishes we have weakly claim
power to cure. If we were scrupulously hones
not lacking in courage, the profession would lon
have refuted the claim to cure syphilis, and h
successfully dealt with all active evidence o
disease, would have addressed their patients in
such as these:—

> "You have been put through a course of treatment
> has been successful in ridding you of all signs of active d
> and experience tells us that if you will submit to som
> syphilitic treatment about twice a year, perhaps a co
> pills or a few injections, you need have no fear of f
> trouble. If you ask me how long this must go on, m
> honest answer must be 'for the rest of your life.'
> have no means of deciding whether you are perma
> cured, and you must regard your periodic courses of
> ment as a method of health insurance with so sound a
> that you will be relieved of all anxiety in regard t
> future. Yes, this line must be adopted even if the W
> mann reaction in your blood is negative. Prevention
> better than cure, and freedom from constant worry is
> than both."

This is the kind of talk suitable for a p
whose primary chancre has just disappeared
treatment; but it would do equally well for a
of syphilitic myelitis or basal meningitis
successful treatment.

In regard to what are known as the parenchym
forms of syphilis of the nervous system, ge
paralysis, and tabes dorsalis, the results of
syphilitic treatment are less constant in
encouragement. The former disease has still
considered as incurable, although I have seen
good results from the administration of pow
antisyphilitic remedies renewed at frequent inte
The length of time which has elapsed since
apparent recovery of the patients is still too sho
enable one to judge whether the remission of
ptoms holds out hope of permanent relief.
remedies have been advocated from time to
only to be discarded after a brief enjoyment of fa
and I am inclined to believe that the malarial t
ment of which much has been heard during the
few years is doomed to share their fate.

### *Tabes Dorsalis.*

With the treatment of tabes dorsalis it is
a different story. In my pre graduate days we
taught that antisyphilitic remedies were us
sometimes even harmful, in the treatment of locon
ataxy. To-day these remedies are coming into
own, and I have no hesitation in subscribing t
view that this disease, in its early stages at any
can be checked and held in check by repeated co
of mercury, or of the arsenical compounds, o
a judicious combination of these metals. Le
choose two out of a large number of cases w
illustrate this principle, each serving to emph
a point of clinical importance.

Case 4.—In October, 1912, nearly 11 years ago, a
man consulted me about pains in his limbs from whi
had suffered for four years and which had been reg
and treated as due to neuritis. A detailed description
pains convinced me that they were the lightning pa
tabes dorsalis which, in my opinion, have features

tinguishing them from pains of other origin. Examination revealed no sign of any organic disease with the single exception that his appreciation of painful stimulation below the knees, on the inner side of his forearms, and on parts of his thorax was slightly less acute than the normal. A history was elicited of a venereal sore seven years previously, for which he had been treated for a month, and the Wassermann reaction of his blood was found to be positive. This patient is to-day a perfectly healthy man who would certainly pass as a first-class life for insurance just as he passed A1 for the army during the war. In the interval he has married, and is now the father of two healthy children. He is a scratch golf player and works very hard at his business, often with insufficient holiday. There can be little doubt that he owes his maintenance of good health to the fact that from the day he came to see me he has never allowed more than a few months to elapse without a course of antisyphilitic treatment, mercurial inunctions varied by an occasional series of injections of novarsenobenzol. May I add that, although the Wassermann reaction has been taken from time to time with varying results, these tests have never been allowed to influence the incidence or character of his treatment.

Case 5.—In April, 1908, I was consulted by a man of 51 years of age on account of lightning pains and some difficulty with vision. He presented unequal Argyll Robertson pupils, normal discs, slight relative analgesia over the skin of his legs, very sluggish knee-jerks, and complete absence of ankle-jerks. Although not in any way ataxic, the postural sensibility in his toes was not up to normal standard. It is interesting to note that this patient is a watchmaker and spends many hours a day doing fine work necessitating a considerable strain on his vision. He is still doing this work to-day and his physical signs have not altered. During the 18 years he has been under my care he has had courses of mercury at frequent intervals and occasional courses of potassium iodide

The first of these two patients has been referred to in order that emphasis may be laid on the possibility of making a diagnosis of tabes from the character of lightning pains before the development of physical signs, and on the success attending early and repeated treatment over a long period of years. The story of the second patient has been recorded with the object of showing that mercury and potassium iodide, if their administration is persevered with, may still be relied upon to hold in check the ravages of syphilis on the central nervous system.

The principles governing the treatment of syphilis of the nervous system do not really differ from those governing the treatment of syphilis of other organs, but in view of the value as well as of the delicacy of nervous tissues the importance of early diagnosis cannot be too strongly urged. If any real advance is to be made in the war against syphilis, it must depend on our having the moral courage to confess to our patients that we are unable to recognise any permanent cure for the disease. I am convinced that if this policy had been adopted when it should have been thousands of lives would have been spared and untold masses of suffering avoided.

## Disseminated Sclerosis.

Disseminated sclerosis has been chosen for very brief consideration in close proximity to syphilis of the nervous system because the two conditions possess many clinical features in common. In both instances the central nervous system is liable to attacks on its integrity which are not in any way regulated as regards time or place. In both we meet with remissions and relapses, but in the case of disseminated sclerosis, recognising as we do the remarkable powers of recovery exercised by Nature alone, it is a matter of great difficulty to estimate the value of any remedial agents we employ. Nevertheless, I have held the view for a long time, and I am not yet prepared to abandon it, that if the principles governing the treatment of syphilis are applied to the treatment of disseminated sclerosis, in spite of our ignorance of its causal agent, the results are often too striking to be disregarded or attributed entirely to the action of chance. Arsenic and mercury are employed more and more frequently in the treatment of this disease, but success, as in the case of syphilis, is mainly dependent on early diagnosis and on the indefinitely continued administration of the two metals just mentioned.

I cannot do better than cite a single case in support of the view that the repeated administration of arsenic, whether by mouth or through the skin, does exercise a beneficial influence on the course of the disease.

Case 6.—In April, 1912, a girl of 17 complained to me that a fortnight before our interview she experienced pins and needles in her right leg followed shortly by a sudden failure of power in her left leg. Three days later her left arm was numb and cold up to the elbow and she suffered from slight headache. On examination, I found the right disc hyperæmic with blurring of its edges. Both hands were lacking in postural sensibility and the left was almost completely astereognostic. The abdominal reflexes were absent on the left side and sluggish on the right. The left leg was spastic with ankle-clonus and extensor response. The power of the right leg was good, but its tactile and painful sensibility was diminished. Her gait was very ataxic.

On my advice she took arsenic in the form of Fowler's solution for three weeks out of every four, and when I saw her next six months later she expressed herself as being as well and as active as before her illness. Her only physical signs then were slight temporal pallor of the right disc, left knee- and ankle-jerks more brisk than right, and an indefinite extensor response in the left foot.

When I saw her next in June, 1914, she was perfectly well and I could find no abnormal physical signs. About two years later she began to neglect her arsenic, and in December, 1917, she came to me complaining that her left leg was weak. Examination showed that the left abdominal reflex was absent and the left plantar response extensor in type. The resumption of arsenic was followed by benefit, and in January, 1918, I could find no physical signs. Six months later she married, and in August, 1920, a healthy child was born. The arsenic was again neglected, and in January, 1922, she developed sensory disturbances in her left leg and loss of power in the right She was put through a course of intramuscular injections of glucarsenol and made a complete recovery. When I last saw her in July, 1924, she was perfectly well and leading a normal active life.

This story may be summarised in a few words. A girl of 17 was crippled by patches of disseminated sclerosis in April, 1912. In July, 1924—12 years later—after experiencing some vicissitudes and taking a great deal of arsenic, she was an active and apparently normal married woman with a healthy child 4 years of age. I am sceptical enough not to be convinced by this story that arsenic has specific powers in combating the disease we call "disseminated sclerosis," but a long experience of its effect in such cases leads me to think that if used early and persevered with it is the best weapon we can employ.

## Conclusion.

In the course of this, my second, lecture I have discussed the treatment of epilepsy, syphilis of the nervous system, and disseminated sclerosis, and have endeavoured to lay emphasis on two principles which are of outstanding importance if any measure of success is to be attained. The first of these is early diagnosis associated with a frank recognition of the fact that preventive measures must be our mainstay in the struggle against the diseases under review. The second principle is that of taking our courage in both hands and, in spite of the public demand for rapid cures, insisting on regulated treatment over long, perhaps indefinitely long, periods of time. Our knowledge of the natural history of these diseases does not permit us to shirk this responsibility or to take a line of less resistance.

---

Glasgow Hospitals.—The annual report of Glasgow Royal Infirmary states that during 1925 more than 70,000 persons in all received attention; this was 1212 more than in the previous year. There were over 35,000 out-patients, an increase exceeding 10 per cent. The average period of residence was 18·2 days, as compared with 19, and the average cost of each patient £7 10s., a fall of 7s. 9½d. In 1890 the average residence was 31 days. The managers are increasingly anxious to relieve pressure and hasten convalescence by establishing a country annexe.—The annual report of Glasgow Victoria Infirmary announces that the governors have purchased 30 acres of land for the establishment of a country auxiliary, and that an early start will be made with the first section. There will be accommodation for 50 patients, and towards the cost of £50,000 Mr. W. Gilchrist-Macbeth has given £20,000.

# THE
# GORILLA AND MAN AS CONTRASTED FORMS.

*Being the Abstract of a Hunterian Lecture given in the Royal College of Surgeons of England on Feb. 26th, 1926,*

By Sir ARTHUR KEITH, M.D.Aberd., F.R.S.,
CONSERVATOR OF THE MUSEUM.

The history of the gorilla, which in a structural sense is man's nearest living relative, is closely linked with the Museum of the Royal College of Surgeons. The first description of the gorilla's skull was given in 1848 by Sir Richard Owen, who was then conservator of the Museum. That master-anatomist was impressed by the resemblance of the skull of the new anthropoid to that of the chimpanzee and came to the conclusion that the gorilla was in reality a highly differentiated species of chimpanzee. Although it is true that the adult males of one breed of chimpanzee may closely resemble the immature male gorilla and also the adult female, yet the expert eye has no difficulty in distinguishing between them. Hence, since Owen's time, anatomists have agreed to raise the gorilla to a separate generic rank. Another link which binds the Museum of the College to the early history of the gorilla is its possession of the first skeleton brought to Europe; Sir Richard Owen acquired it from Captain Harris in 1851. Lately several valuable additions have been made to the gorilla collection of the Museum. The African traveller, Mr. F. W. H. Migeod, had presented the skulls of two adult males obtained in that part of West Africa where the French Cameroons marches with British Nigeria, but on the French side of the frontier. These are the "furthest north" gorilla skulls which have come from Africa. Through Lieut.-Colonel R. H. Elliot the College have obtained skulls of that peculiar breed of gorillas which live in the mountainous regions between Lake Tanganyika on the south and Lake Edward on the north, and was first made known from the region of Lake Kivu by a German engineer in 1902, and hence is known as the Kivu gorilla. Colonel Elliot's specimens, one the skull of a gigantic male, the other that of a youth, come from the Congo frontier of Uganda and are the "furthest East" specimens which have come to Europe. Another African traveller, Captain J. E. T. Philipps, has collected a series of Kivu skulls in the south-western corner of the Uganda Protectorate, which have been presented to the Natural History Museum, South Kensington; the lecturer has been given free opportunities of examining Captain Philipps's specimens and of comparing them with those in the Museum of the College. The most valuable addition to the gorilla series of the Museum, however, has been made by the President of the College, Sir John Bland-Sutton. He acquired and presented a series of skulls and skeletons, collected in the Cameroons, to illustrate the remarkable growth and age changes which the gorilla passes through in its passage from youth to old age.

### *Distribution of the Gorilla.*

Thus the homeland of the gorilla extends across equatorial Africa from Nigeria in the West to Uganda in the East, a stretch of 1500 miles. But although the gorilla homeland is wide, its population is represented only by scattered and small family bands; from accounts furnished by travellers and hunters, one infers that the total population—males, females, and young—is well under 10,000. Spread over so wide a space one would expect to find well-differentiated local breeds or even species. There are only two breeds or races—the highland or Kivu race and the lowland or Gaboon race. The highlander lives on the brush and thickets which clothe the gullies and steep sides of his native mountains. The climate of his homeland, although on the equator, is wet, cloudy, and bleak; the Kivu gorilla lives at an altitude about 10,000 ft. above sea-level. Hence the highlander is provided with a longer and denser coat of hair than his lowland cousin. So distinctive are these two breeds—the highland and lowland—in external appearances that one expected to find differential marks in their skulls, and yet a prolonged search has failed to reveal any constant point of structural difference. It is true that the highlander is usually the larger and stronger animal; a male shot by Mr. Carl Akeley weighed 32 st. (205 kilos); the skull presented by Colonel Elliot has larger teeth and jaws than has ever been seen in a lowland form, yet among the highland skulls collected by Captain Philipps some are not above the lowland standard. One distinction is almost constant in the symphysis of the lower jaw of the Kivu gorilla. The genioglossus muscles of apes arise from a pit behind the symphysis. In the lowland gorilla this pit is usually large, in the highland gorilla it is usually filled up by bone, as is the case in all recent races of mankind.

Although the failure to find any constant anatomical difference between the lowland and highland races of gorilla may upset the systematic zoologist, it is of the greatest interest to the student of human races. For he is familiar with the fact that men of the same race show an extraordinary variability in their facial features, and also in colour of skin and hair. Such a variability is usually explained as being due to a mixture of race; amongst gorillas the degree of variability is even greater, but amongst them there can be no suggestion of mixture of race. In both cases the degree of variability may be taken as evidence of an evolutionary plasticity. For on the evidence provided by geology we may presume that man and the gorilla are both evolving, but in opposite directions, the one towards brain, the other towards brawn.

### *The Gorilla's Gait.*

Both Lamarck (1809) and Darwin (1871) supposed that if an anthropoid ape became, either from choice or necessity, a ground-living form it would, in the course of generations, acquire a human gait. A little reflection will convince anyone that an animal weighing 30 st., such as the male gorilla, must be a clumsy climber; its flight would be limited to such trees and branches as could carry so great a weight. Mere weight compels the adult male to a life on the ground. From the accounts which have come home from hunters and travellers we now know that gorillas are, particularly the adult males, ground-living forms, and apparently have been such for many a generation. Yet the gorilla still walks with a forward slant in his body, supporting and balancing his weight on his bent knuckles as he advances. His feet, it is true, have advanced nearer to a human shape than those of any other known ape. The essential structural characteristic of the human foot is the relatively great size and length of its tarsal element and the relative shortness of the outer four digits. In this respect the gorilla's foot stands intermediate to that of the chimpanzee and of the human child.[1] And yet the great toe of the gorilla can be, and is, used as a grasping thumb. Recently an animated discussion took place in the pages of *Nature* (Sept. 24th, 1923, et seq.) between Sir E. Ray Lankester and Dr. W. K. Gregory, of the American Museum of Natural History, as to whether or not a cast of the foot of a Kivu gorilla, which showed the great toe in alignment with the other toes, as in the human foot, could be regarded as a true or natural representation of the position of this digit. Both abducted and adducted positions are natural for the great toe of the gorilla; when the animal scrambles in thickets of bamboo in search of its favourite food—young bamboo shoots—it uses its foot as a grasping organ; when it waddles along the glades which intersect the undergrowth of its native jungle the foot is used as a supporting and propelling structure. The great toe falls into alignment with the other toes and becomes the chief point from which the forward impetus is obtained. Flexion lines, corresponding to those of the gorilla's foot, are to be seen on the sole of every newly-born child. Dr. T. Brushfield has recently recorded their presence in the feet of mongolian idiots of juvenile age. A strict comparison of the structural characters of the feet of man, the gorilla, and the chimpanzee, leaves the anatomist convinced that the human foot, in the course of its final evolution, passed through a gorilline stage.

---

[1] See Keith: Evolution of Man's Posture, Brit. Med. Jour., 1923, i., 670.

### *The Affinities of the Gorilla to Man.*

This conviction is strengthened by certain other anatomical features of the gorilla's body. In early days of the Darwinian struggle opponents of the evolutionary theory laid much stress on the fact that man had a special muscle—the peroneus tertius—for raising the outer border of his foot, and that the muscle was his peculiar possession. We now know that the peroneus tertius is not constant in human anatomy; if a hundred bodies are dissected there will likely be five in which this muscle has not been separated from the long extensor of the toes, and ten in which the separation is only partial. European anatomists have known for many years that partial attempts to form a peroneus tertius do occasionally occur in the gorilla, but in only one case has a fully differentiated muscle been found. Recently, however, Dr. Dudley Morton,[2] on dissecting two gorillas, one of which belonged to the Kivu breed, found this muscle differentiated in both animals. It is difficult to think that the tendency to produce this muscle has arisen independently in two forms which are so near akin in structure and origin as man and the gorilla; one cannot conceive that using the foot in a plantigrade position would cause the outer part of the long extensor of the toes to split away from the rest and bring about a migration of the tendon of the separated part backwards along the outer border of the foot. What causes such useful variations to arise we do not know, but the tendency to produce the one in question is found in only man and the gorilla, and points to an inheritance from a common ancestor.

Such an intimate structural resemblance between man and the gorilla does not stand alone. In lower primates the origin of the soleus muscles of the calf of the leg is confined to the fibula; in man this origin has been extended to the whole length of the oblique line of the tibia. A tibial extension is to be found in 35 per cent. of gorillas and in a lesser percentage of chimpanzees. The extensor brevis pollicis is another muscle which has not become firmly fixed in man's body; it has arisen by the separation of part of the extensor ossis metacarpi pollicis; in 6 per cent. of white men and in a larger percentage of negroes this muscle, which was regarded as peculiar to humanity, remains undifferentiated or only partly separated. The only other animal which shows a tendency to produce this muscle is the gorilla; a representation of it is found in 20 per cent. of the animals dissected. On the inner side of man's upper arm is found the fibrous remnant of a climbing muscle—the latissimo-condyloideus; in 5 per cent. of human bodies muscle-fibres occur in this remnant. The latissimo-condyloideus is more reduced in the gorilla than in any other anthropoid; in 20 per cent. of dissections the muscle is represented, as in man, by fibrous tissue only. When we take into consideration these intimate resemblances between man and the gorilla, and keep in mind that this anthropoid makes a nearer approach in size and pattern of brain to that of man than any other known animal, the conviction is forced home that the gorilla has come by a larger share of man's inheritance than any other ape. In this matter the gorilla's cousin, the chimpanzee, is his nearest rival.

### *The Trend of Evolution in the Gorilla Contrasted with that in Man.*

The brain of man forms the climax of an ascending series. Between the stage represented by the brain of the marmoset and that exemplified by the gorilla a series could be chosen which would exemplify every grade of evolution. The skull of the adult male Kivu gorilla obtained by Colonel Elliot has a capacity of 620 c.cm.; some are known in which the capacity reaches 650 c.cm. Between the highest gorilla and the lowest human brain we know as yet only one intermediate stage—that represented by the brain of Pithecanthropus, and in size and pattern this brain has reached almost, if not quite, the threshold of humanity. The point of brain development reached by the human brain marks the furthest point attained by any primate, but in weight of body, in volume of lung, in size of tooth, massiveness of jaw, and strength of muscles—particularly those of mastication—the gorilla crowns the primate series. We have found no fossil remnant of any anthropoid which was so massively developed as is the gorilla. And yet at birth the gorilla is smaller (under 5 lb. in weight) than the new-born child, and is just as nude and helpless. Its skull is as rounded and smooth as that of a human infant, and the muscles of mastication are no larger. The temporal muscles, for example, start from the same base line on the sides of the skulls of the gorilla, chimpanzee, and man, but whereas the temporal muscles of the gorilla extend their origin until great bony crests are formed along the vault of the skull, those of the chimpanzee and of man stop short of such an extreme. In man the temporal muscles are arrested in their ascent at a stage corresponding to that reached by the gorilla in youth; in the chimpanzee these muscles become arrested at a point reached by the gorilla in early adolescence. In man the evolutionary tendency has been to retain more and more the structural characters of youth; in the gorilla the tendency has been in the opposite direction—to increase the size of jaw and strength of body. In his evolutionary career man has moved in the direction of brain, while his cousin the gorilla has moved in the direction of brawn. The evolutionary process which has produced such diverse forms from a common ancestor constitutes at once the most enigmatical and also the most interesting experiment to be found in the whole realm of Nature.

### *The Machinery of Evolution.*

Dr. W. A. Freund,[3] in 1872, when describing a patient, who, as we now know, was the subject of acromegaly, was struck by the fact that the structural changes to be seen in the body of his patient were anthropoidal in character. Dr. Harry Campbell in 1894, when the relationship of acromegaly to a disordered action of the pituitary gland was beginning to be recognised, observed that men and women who became the subjects of acromegaly underwent growth changes which were similar in nature to those which occur in the maturing phases of the gorilla. He was inclined then to explain acromegaly in man as an atavism or reversion to an ancestral or evolutionary stage—one which is now represented in the bodies of gorillas. It seems more legitimate, in the present state of our knowledge of the action of hormones on the growth of the body, to regard gorilline characters, whether they occur as a normal manifestation in the life-history of the gorilla or as an abnormal manifestation in the life-history of the acromegalic, as being due to an increased action of that element of the pituitary gland which influences the processes of growth. Those who oppose such an explanation on the grounds that no proof has been adduced that the pituitary gland of the gorilla is exceptionally large, forget that our recognition of pituitary influence cannot be inferred from the size of the pituitary gland. The pituitary is a complex body producing many substances, some of which subserve immediate physiological purposes; others can somehow stimulate and regulate the growth of diverse anatomical systems of the body. The anatomist cannot assess the functional potentiality of a pituitary gland by the crude use of scales or microscope.

---

[3] See Keith: The Nature of the Skeletal Changes in Acromegaly, THE LANCET, April 15th, 1911; Progeria and Ateleiosis, Ibid., Feb. 1st, 1913.

There is an infinitely more delicate method. The pharmacologist recognises the presence or absence of one element secreted by the pituitary gland by its influence on the contraction of non-striated muscle. The clinician recognises the action of another element formed by the pituitary gland by its influence on the growth of the muscular, bony, and alimentary systems of the living body; he discovered these effects by the study of cases where the action of the pituitary becomes disordered as in the subjects of acromegaly. It is just those systems which undergo so great a degree of increase during the later stages of growth of the gorilla. We may therefore legitimately infer that, in the evolution of the gorilla, the pituitary has played a prepotent part. The evidence, as it stands, is enough to justify the student of man and ape in believing that he has obtained a real glimpse into the machinery of evolution.

# ASSOCIATED ORGANISMS CAUSING EMPYEMA.

By H. E. A. BOLDERO, D.M. OXF.,
M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, MIDDLESEX HOSPITAL; PHYSICIAN,
EVELINA HOSPITAL;
AND
L. E. H. WHITBY, *M.C.*, M.B., B.CH. CAMB.,
ASSISTANT PATHOLOGIST, MIDDLESEX HOSPITAL.

INTEREST in the following case of empyema lies chiefly in the fact that two organisms were associated in its production; the one a mycelium, and the other a pneumococcus. Alone neither was pathogenic to guinea-pigs, but in association they always produced lesions. Clinically, the striking feature of the case was its chronicity. Probably the start of the empyema can be dated from an "attack of pneumonia," which occurred five months before the patient came under observation. He was in the ward for a further three months, and during that time was never urgently ill, nor did he show marked signs of toxæmia.

### *Clinical History.*

The patient was a man, aged 19, admitted to the Middlesex Hospital under Dr. C. E. Lakin in February, 1924. In the history there is little to note. As a child he made a good recovery from an attack of measles, and was free from any illness until September, 1923. In September, 1923, he had "pneumonia" at home, from which he "improved very slowly," his cough and expectoration persisting until admission. On admission the patient looked pale and seedy, but was not urgently ill. He was more comfortable lying on his left side. The temperature chart showed very slight irregular fever in the neighbourhood of 99° F., while the pulse-rate varied between 90 and 100. Slight clubbing of the fingers only was present. There was no cyanosis or respiratory embarrassment. His cough was only troublesome at intervals, and the sputum was muco-purulent, greenish in tinge, and did not exceed 2–3 oz. a day. Typical signs of empyema in the left pleural cavity were found, the heart's apex beat being 2¼ inches from the mid-sternal line. X ray examination confirmed the clinical findings. With an exploring needle a few c.cm. of pus were withdrawn. It was thick and of a greenish-yellow tint. One of us (L. E. H. W.) examined this pus and found the predominating organism to be a mycelium, but there were also present a few pneumococci. The patient's blood showed a leucocytosis of 22,500 per c.mm., of which 68 per cent. were polymorphonuclear cells. The Wassermann reaction was negative, so also was the tuberculous complement-fixation test. The sputum contained neither tubercle bacilli nor any mycelium.

Aspiration was decided upon, and 17 oz. of pus were removed. The patient improved rapidly, putting on 8 lb. in weight during the following week. The physical signs at the left base showed that the fluid was clearing, particularly behind, near the spine. After two or three weeks, however, little change was appreciated in the physical signs, for the absence of breath sounds and the marked dullness on percussion (more particularly in the left lower axillary region) persisted. The apex beat was now 3¼ inches from the mid-sternal line. Rib resection was not undertaken as the patient's general condition continued to improve. He was given small doses of potassium iodide three times a day for six weeks.

The sputum, having been examined regularly, was found three weeks after aspiration to contain a mycelium apparently identical with that obtained from the pleural cavity. It is to be noted that the sputum had not increased in quantity nor changed in naked-eye appearance. Further progress was slow and uneventful, and the patient was discharged in May, 1924. When next seen in August he said he was "feeling well," and the physical signs showed no evidence of fluid, but the air entry into the left lower lobe was still very poor. His fingers showed the same slight degree of clubbing.

Over a year later, in October, 1925, in response to a query, he wrote: "I have not required any medicine since October, 1924, and have been at work since January, and feel very well—in fact, better than before my illness."

*Bacteriological Findings.*—The specimen of pus aspirated from the pleural cavity was thick and of a greenish-yellow colour. Careful search failed to reveal any of the macroscopic sulphur-yellow "granules" characteristic of true actinomycotic infections. In stained films of the pus the predominant organism was found to be a mycelium the threads of which were often of considerable length, many of them showing segmentation of the protoplasm and the presence of the so-called "spores"; but neither branching of the mycelium nor clubbing of the ends could be observed. A few encapsuled pneumococci were also present. In culture the mycelium grew in about a week under aerobic conditions on ordinary agar, the colonies being small, opaque, and difficult to pick off with the needle. The threads in culture were shorter, thicker, and more bacillary in form than those in the original specimen. Neither the original mycelium nor the culture was acid-fast.

With a view to testing the pathogenicity of the organisms, three guinea-pigs were inoculated subcutaneously with 2 c.cm. of the undiluted pus. Within a week all three animals had developed at the site of the inoculation hard subcutaneous inflammatory masses, about the size of a half-crown. There was no glandular enlargement. A post-mortem examination on one of these animals showed considerable subcutaneous œdema with slight hæmorrhages at the site of inoculation, and a small abscess cavity containing no organisms in films or cultures. Some of the tissue from this animal was macerated in saline and inoculated into a further guinea-pig, but failed to produce any lesion. The two other animals of this series were allowed to live and in three weeks had entirely recovered; when finally they were killed, at the end of six months, no tuberculous lesions were found. A further guinea-pig was inoculated subcutaneously with 2 c.cm. of a fresh specimen of the pus, and in ten days had developed a discharging sinus, the discharge containing a few mycelial threads, but no pneumococci. This finding was verified by culture. Sections of the skin and subcutaneous tissue from this animal showed much inflammatory reaction with the presence of occasional mycelial threads.

As experiments with the original specimen showed that lesions could be produced in the guinea-pig, it was decided to try the effect of inoculation with pure cultures. A further series of three guinea-pigs was inoculated subcutaneously as follows: (1) with 2 c.cm. of a strong emulsion of the pure mycelium; (2) with 2 c.cm. of a strong emulsion of the pure pneumococcus; (3) with 2 c.cm. of a mixture of the two emulsions in equal parts. Of these animals, the last-named only developed a hard subcutaneous inflammatory mass, similar to that produced in the animals inoculated with the original specimen of pus. The lesion was most marked on the tenth day and had entirely subsided at the end of three weeks. The other two animals showed no lesion at all. The experiment was repeated on a further series of these animals with the same result, except that the lesion was extremely small and had disappeared in a fortnight. The pathogenicity of the pneumococcus was tested on a mouse by the intraperitoneal inoculation of an agar slope of the pneumococcal culture. The animal survived the inoculation and showed no sign of illness at any time.

### *Conclusions.*

The result of the animal experiments indicates that the two organisms—mycelium and pneumococcus—when associated together were capable of producing lesions, but that when separate they were incapable of so doing. There was no suggestion throughout the entire investigation that the mycelium should be classed with the streptothrix actinomyces as described by Homer Wright.[1] The mycelium had the characters, both morphological and cultural, of the organism of Boskröm, usually regarded as a secondary and non-pathogenic invader from the mouth. In this patient the empyema was probably pneumococcal in origin, as he had "pneumonia" five months before admission to hospital. It would seem logical to infer that the empyema tended to be more chronic and stubborn owing to the superadded infection with the mycelium—probably arising from the mouth. In these circumstances aerobic oral mycelia can hardly be regarded as entirely non-pathogenic.

---

[1] Biology of the Micro-organism of Actinomycosis, Jour. of Med. Research, 1904.

Symbiosis of micro-organisms is a well-recognised fact. The organisms of gas gangrene thrive well in a wound infected also with pyogenic cocci. The *B. influenzæ* (Pfeiffer) is considerably assisted by the presence of concomitant staphylococci and pneumococci. Again, the streptococcus has been shown by Gaté Papacostas and Billa[1] to increase the toxin production of the diphtheria bacillus. In our case we are justified in assuming that an originally non-pathogenic mycelium was capable of pathogenicity when associated with a pneumococcus—even though the latter had apparently become avirulent.

We are indebted to Dr. Lakin for his kindness in allowing us to publish this case.

# ENCEPHALITIS FOLLOWING OPERATIONS ON THE TEMPORAL BONE.

By J. ARNOLD JONES, O.B.E., M.B. Manch.,
F.R.C.S. Edin.,

SURGEON, ST. JOHN'S HOSPITAL OF MANCHESTER AND SALFORD FOR DISEASES OF THE EAR; SURGEON IN-CHARGE, NOSE, THROAT AND EAR DEPARTMENT, ROYAL MANCHESTER CHILDREN'S HOSPITAL.

Encephalitis resulting from an operation on the temporal bone must be a very rare condition, as a search through literature discovers no references. Two such cases have occurred within my own experience, the first under Mr. Macleod Yearsley when I was house surgeon to the Royal Ear Hospital, and reported by me in The Lancet, 1900; the second, a private patient on whom I performed a radical mastoid operation in September, 1922. As regards the first case, it suffices to say that although the encephalitis was the predominant complication, it was accompanied by an abscess in the temporo-sphenoidal region; that the patient was in a condition of acute maniacal delirium for over three weeks; that a large hernia cerebri developed and that recovery eventually took place.

In the second case encephalitis alone was present, the symptoms were much less severe than in the first, and complete recovery took place. The history of this case is as follows.

Mr. A, aged 38, consulted me in regard to a chronic discharge from the right ear of over 23 years' standing; deafness was also complained of. On examination almost total destruction of the drum and ossicles was observed, together with the presence of much tenacious pus and debris; no pain or tenderness was present.

*Operation.*—On Sept. 10th, 1922, I performed a radical mastoid operation. The antrum and middle ear were full of pus and cholesteatomata; the bony roofs of both cavities were missing. On closer examination it was found that while the meninges formed a roof to the tympanic cavity they were missing from over the antrum, and brain tissue was actually protruding into that cavity in fair quantity. The operation was performed on the usual lines and all cholesteatomatous and septic material was thoroughly removed from the antro-tympanic cavity. A meatal flap was formed and the cavity packed with gauze soaked in iodoform emulsion. The post-aural incision was sutured. The night of operation the temperature rose to 101° F., but was normal next morning and remained so until the fifth day. During this period the patient's general condition was quite satisfactory and he complained of no local pain or headache. The nurses thought that occasionally "he seemed a little bit queer" mentally. On the fourth day the first dressing was done and everything found perfectly satisfactory. On the evening of the fifth day the temperature rose to 100° and he was restless. Next morning the temperature remained at 100°, and he was very mildly delirious, but complained of no pain or headache. On the evening of the sixth day the temperature rose to 102·4° and he was definitely delirious and restless; bromides were given. From now until the twenty-eighth day the temperature varied from 100° to 103·6° with an occasional drop to 99°. The pulse, which was 74 before operation, varied from 60 to 80, while respirations, usually 24, never reached higher than 28. He only complained of headache three times, but it was apparently not severe in degree. He vomited twice, on the seventh and the twenty-eighth days. During the whole period from the fifth to the twenty-eighth day he was more or less delirious, usually mildly so during the day, more markedly so at night, when he had to be controlled by drugs, but his condition never passed into that of stupor. At no time was there rigidity of the neck muscles, nor was Kernig's sign ever present. The local condition was always satisfactory. The post-aural incision healed by first intention. Packing the antro-tympanic cavity was discontinued on the eighteenth day, and subsequently a daily toilet was performed, consisting of syringing the cavity with boric lotion and afterwards instilling 50 per cent. spirit lotion. On the twenty-ninth day he left the nursing home and passed under the care of his own medical adviser.

I next saw him on Dec 10th, 1922—i.e., about two months later—and found him in a very satisfactory condition. He was in perfect health and the antro-tympanic cavity was dry and completely lined with white shining epithelium.

The diagnosis of encephalitis was made because the symptoms did not fit in with any other intracranial complication, and because the presence of brain tissue in the antrum obviously lent itself to injury or infection. The symptoms which characterise simple uncomplicated encephalitis would, therefore, appear to be pyrexia of some weeks' duration accompanied, by delirium more or less marked. The patient at no time appears very ill. The prognosis would appear to be good. If other complications arise, as in the first case referred to, in which a temporo-sphenoidal abscess was present, other and more serious symptoms will appear. Post-operative encephalitis of this type can only arise when the brain tissue itself has been injured. In my experience this has happened on two occasions, in both of which chronic mastoid disease had destroyed not only the bony roof of the antrum but also the meningeal covering of the brain, allowing the substance of the latter to project into the antral cavity.

It is extremely difficult in these cases to remove the septic contents of the antrum without damaging the brain tissue to some extent, and the degree of encephalitis that follows seems to me to depend upon two factors: (1) the amount of trauma inflicted on brain tissue; (2) the thoroughness with which the antro-tympanic cavity is cleared from infective material. The accomplishment of this latter object is much facilitated by the use of properly made iodoform emulsion used as a dressing.

**A School for Myopes.**—Mrs. Bridge, B.A. Lond., formerly principal of a school in Brighton, has opened a school for myopes at the Manor House, Piltdown, near Newick and Uckfield, Sussex. The aim of the school is to educate children with defective eyesight. The teaching is largely oral, and practical and concrete methods are adopted wherever possible. Much time is spent in the open air and sedentary work is reduced to a minimum. The schoolroom is specially built for the purpose and suitably fitted. The special desks used in the L.C.C. myope schools are used. The curriculum includes dancing, eurythmics, musical appreciation, and certain handicrafts, beside the usual English subjects and French. Advantage is taken of the wireless and of good gramophone records. Outdoor occupations and interests, such as gardening, poultry keeping, pets, &c., and simple home duties, alternate with the ordinary lessons, so that the time which may not be spent in reading is both usefully and happily occupied. At present only ten children can be received. They share the home life of the principal's own children, on whose account she first made a study of the need of special education for myopes.

### Testing of Renal Function

in relation to the treatment of renal disease. It was important, he said, to reduce the number of tests to a minimum, and all necessary information could be gained from the estimation of the blood-urea and the urea concentration in the urine. The blood-urea was variable; 20 mg. was about the normal for young people, but it might reach 80 mg. in healthy people past middle life. Many conditions other than kidney trouble could increase it, and alone it was unreliable, except that if it were normal the kidneys could not be in a very bad state. The water test, extensively used in America, gave much trouble to the patient but no more information to the doctor. The simplest test of all was to starve the patient of fluid from 15–20 hours and then estimate the urea in the urine by the hypobromite method.

*Albuminuria and Hæmaturia.*—Albuminuria was common; it hardly ever led to nephritis in children. The patient was usually a bit overgrown and neurotic and the urine showed no casts. In such a case the albuminuria meant nothing. Adults might have albuminuria and even casts without any symptoms of disease and with repeatedly normal readings in the urea tests. Another type of patient passed albumin, casts, and blood, and definitely had something wrong, probably a mild attack of acute nephritis. Recovered cases of nephritis might improve in their urea concentration from 1·3 to 4 or 4·5 per cent. and still have some albuminuria. Continuance of the albuminuria was, therefore, no indication that the kidney was passing into the chronic condition. Some perfectly healthy people continued to pass albumin for 20 or 30 years after an attack of scarlet fever. It was important to examine the centrifugalised deposit. He cited the case of a small boy with curious attacks of pallor, pain, and some difficulty of micturition. There was no evidence of nephritis, but the centrifugalised deposit of his urine was full of cystin crystals.

*High Blood Pressure and Nephritis.*—Boys of 16 to 19 often passed a little albumin and had a blood pressure of 155/80. In most of these cases there were no subsequent developments. Many healthy people had abnormally high blood pressures without symptoms of ill-health. If the kidneys got involved when the high pressure occurred with arteriosclerotic changes, the end was not far off, but they often escaped, even when the veins of the arm were twisted and swollen.

*Treatment.*—Nothing much could be done in acute or chronic nephritis, said Prof. MacLean, except to put the kidneys under the best possible conditions. The patient should be kept warm and given glucose by the mouth. Many who could not drink milk could take a 50-per cent. solution of glucose, which passed so quickly into the intestine that a certain amount was retained even if the patient vomited. Diuretics were of no use; there was already an excessive amount of urea, which was the best diuretic known. In the parenchymatous type, where the patient had a tremendous œdema and was passing protein in the urine, a good solid diet with plenty of protein was beneficial. 80–100 g. doses of urea sometimes promoted diuresis, which very often hung suspended on a trigger and was released by most unexpected factors. Baths were sometimes helpful, and nicking with a knife was better than Southey's tubes. There was no evidence that protein did any harm whatever. Animal experiments showed that a rabbit would not develop nephritis even on a diet containing 70 per cent. of protein if it were also given green vegetables in minute amounts. It was better to reduce the protein in very acute nephritis, but in advanced chronic cases it did not matter. It was wrong to interfere with a high blood pressure; the body became accustomed to it and the patient was better left alone, unless it was causing definite symptoms.

*Discussion.*

Sir **Thomas Horder** said that he was unable to believe in the wisdom of reducing the tests of renal function to a minimum. The condition of nephritis was so complex, being possibly not a disease at all but a general metabolic disturbance which produced kidney changes amongst other effects, that we might be "caught out" if we reduced the tests of a single organ to a minimum. It was premature to say which were the best tests. The significance of casts depended on the criterion of the examination. He had given up attaching importance to casts found after careful examination of a centrifugalised deposit. In many cases nephritis progressed very slowly indeed, if the patient escaped secondary infections like subinfection of the alimentary tract, mild sore-throat, coryza, &c. Acute nephritis was very often an exacerbation of the kidney condition due to such infection. A scarred kidney revealed only by albuminuria was not uncommon. The present generation tended to hustle their renal cases too much or to be disappointed too soon; in the old days renal patients were carefully nursed for months. Sometimes decapsulation would start a diuresis which, once obtained, might go on. Possibly the recovery obtained in chosen cases might be due less to the actual decapsulation than to the escape of fluid by the incision, and other operative procedures might do as well. He agreed with Prof. MacLean about the diet in chronic cases. There was as yet no rational pathogenesis of nephritis; how, therefore, could there be a satisfactory therapeusis?

Sir **John Thomson-Walker** dealt with the surgical side of the problem, which was largely concerned with cases of enlarged prostate, and in 80 per cent. of cases dealt with a temporary condition where the renal function would be almost entirely recovered in ten days with proper treatment. He had always suspected that the good effect of decapsulation in œdematous cases was due to the incisions. He agreed with the desirability of reducing the tests, and believed in the urea tests as opposed to the colour tests—viz., phenolphthalein and indigo-carmine. The urea-concentration test forced the kidney to work up to its highest power, which was what the surgeon wanted to know. The decision for or against operation depended on: (1) The ability of the surgeon to avoid complications; if a patient with a low urea function got bronchitis, hæmorrhage or a little temperature it would be sufficient to kill him. (2) The surroundings of the patient and the experience of the nurse. The blood-urea was only a guide where half the kidney tissue was destroyed, and it gave a good idea of the progress of a case. He had no faith in renal indices; he wanted to know how much blood-urea there was and what the kidney could be forced to eliminate.

Sir **William Willcox** agreed that the two urea tests were the most important, but pleaded for the estimation of the chlorides in urine as almost equally important. They were always below 0·5 per cent. when the kidney was damaged, and might fall to 0·01 per cent. in water-logged cases. Prognosis in nephritis was extremely difficult, for cases varied enormously. "Trench nephritis" cases might clear up completely in a few months, but civil cases ran a very chronic course. He regarded kidney disease as analogous to asthma and hay fever—a sensitisation of the kidney tissue to some particular toxin, for instance, streptococcal sore-throat. It was extraordinary how sensitive the kidney might be and how varied its response. Patients should be given hospital treatment for many months. The symptoms did not go pari passu with the blood-urea, but urea tests were valuable in distinguishing between renal and cardiac cases. He thought that chronic dropsical cases might sometimes be syphilitic.

Dr. J. W. McNEE agreed with Sir Thomas Horder that it would be a pity to reduce the tests to two and forget how crude they were. Extra-renal factors such as diet, failure of the liver or cardiac disability counted in them for a great deal. He regarded the blood-urea as valuable, not as a single estimation, but as a constant guide to the progress of the case. The urea-concentration test, unfortunately, did not always give the information required of it. The water-concentration test was easy and often most informative; it showed if the kidney had lost the power to concentrate, and distinguished between the high blood pressure conditions and true chronic nephritis. The blood-creatinin test was also useful. Frequently a case would get much better within a few weeks and the albuminuria be reduced to ½ or 1 per cent., but there the child would stick and continue to show casts. The attitude of the doctor should be to expect a complete cure in the majority of his cases, and he should go on trying for it until there was other evidence to show that the case had gone on to a progressive nephritis. A valuable sign of this was the appearance of fatty casts containing doubly refracting fat. He regarded diuretics as "hit or miss" drugs, possibly entirely non-specific, and began always by giving a fair trial to those least likely to do harm. He had found that better results followed the low protein diet given in America than the more haphazard diets of this country. Chronic cases often did best on a mixed average diet.

Mr. CYRIL NITCH dealt with the surgical aspect, and said that he relied most on the urea-concentration and blood-urea tests, but regarded the clinical condition of the patient as a third test of equal importance. He only used indigo-carmine when it was inadvisable to catheterise a ureter; it was not very reliable. Specimens for urea-concentration tests should be collected by an indwelling catheter, as residual urine would vitiate the findings. He did not think the blood-urea figure of much value unless it was over 50 mg. per 100 c.cm., when it was a contra-indication to operation. He quoted two cases showing that the concentration of urea was not a reliable guide to prognosis, but he would not care to operate if the figure were lower than 1·7 per cent.

Dr. GEOFFREY EVANS pointed out that the use of these tests was to test renal function, not the fact of renal disease; they were no use for the diagnosis or prognosis of early kidney disease, as they were only positive when the reserve of the organ was lost. Nephritis might go on for five years without failure of renal function. More important than the symptoms of failure of renal function were the signs of renal disease, such as hæmorrhages—in kidney, retinæ, uterus, &c. Marked albuminuria was a significant indication of active disease. When looking for casts it was important to see that the urine was fresh and not very dilute. The most important part of the treatment was lengthy rest in bed, up to 12 months if necessary, at any rate until there were no red blood cells in the urine. Once a patient got well he remained well. Obvious septic foci should be removed. Too little was known about diuretics for a pronouncement on their value or harm. Diuresis might depend on extra renal factors, as had been shown by recent experiments with "euphyllin," a diuretic which worked by causing a discharge of chlorides from the cells and their accumulation in the blood.

## SECTION OF COMPARATIVE MEDICINE.

A MEETING of this Section was held on Feb. 24th, with Mr. F. T. G. HOBDAY, the President, in the chair, when Dr. P. H. MANSON-BAHR read a paper on the

*Relation of Wild Animals to Certain Diseases of Man.*

He said that nowadays it was only in the tropics that man still came into the necessary prolonged and intimate contact with the fauna of his neighbourhood and so became a prey to their disease germs. It was probable that the virulence of these germs was originally much greater and that a state of harmony between host and parasite had been gradually attained, the germ retaining its virulence for non-immune individuals. The susceptibility of man to parasitic diseases of animals was strong evidence in favour of the Darwinian hypothesis.

*Trypanosomiasis.*—The various trypanosomes had become adapted to apparently harmless existence in the blood of many varieties of animals, especially in Africa. Man had become infected only with *T. gambiense* and *T. rhodesiense* in Africa and with *T. cruzi* in South America. The range of sleeping sickness was co-terminous with that of the definitive host, the tsetse-fly. There was much evidence that the infection was now essentially spread from man to man, but Speke's sitatunga, a handsome antelope which had been found naturally infected, was admirably adapted to act as a reservoir of the trypanosome by its wary habits and its range in dense and impenetrable papyrus on the lakes and swamps of Eastern and Central Africa. The sleeping sickness of *T. rhodesiense* was a more rapid, fatal, and resistant form than that of *T. gambiense*, and its distribution corresponded very closely to that of the tsetse of big game. The trypanosome of the big game in this area was indistinguishable morphologically from *T. rhodesiense*, and some observers believed them to be identical. The common waterbuck, the reedbuck, and the duikerbuck were commonly considered to be the reservoir hosts of *T. rhodesiense*. The disease produced by the South American trypanosome was a chronic or acute disease of a myxœdematous character, chiefly seen in children, and the definitive host was a curious reduviid bug, *Triatoma megista*, which was often found naturally infected and lived on armadilloes. The other reservoir hosts were the Azara's opossum and the rock cavy of Brazil.

*Leishmaniasis.*—The peculiar distribution of kala-azar and its association in the Mediterranean basin with a similar infection in dogs indicated that it was in some way connected with a free-living reservoir host. It was communicable to laboratory animals, jackals and monkeys with difficulty, but recently Smiley, Young, and Meleney had found that the hamster was readily susceptible, and that an enormous proliferation of the parasite took place within this animal, without apparently affecting its health. Possibly, therefore, the parasite was transferred to man from this small rodent through the agency of a biting fly such as Phlebotomus.

*Leptospiral Infections.*—Weil's disease was described in 1880, and its parasite in 1916. The *Leptospira icterohæmorrhagiæ* had since been found to exist normally in the urinary tubules of the European rat and Japanese field vole. A young fox was recently found naturally infected near Mill Hill, and captive animals might contract the disease through eating infected rats. Infected hosts passed the organism in the urine, and spirochætes of this type had recently been found widely distributed in water. Why the closely related *Leptospira* of yellow fever was a parasite of man only was a matter of much interest; probably the reservoir animal had yet to be discovered. The *Leptospira hebdomadis* of the seven-day fever of the Japanese lived similarly in the urinary tract of the common field vole, *Microtus montebelloi*.

*Rat-bite Fever.*—The spirillum of this world-wide disease was transmitted by the brown rat (*R. rattus* and *R. alexandrinus*) and was probably identical with *Spirillum laverani* and *Spirillum muris*, commonly found in the blood of rats and mice. The bite of the ferret and domestic cat had also been incriminated.

*Rocky Mountain Spotted Fever.*—This severe typhus-like disease was endemic in limited districts of Montana, Idaho, and Wyoming. The causative *Dermacentroxenus rickettsi* was conveyed by the bite of a local tick which commonly infested the Rocky Mountain goat, badger, lynx, bear, coyote, and other animals. The larval and nymph stages of the tick developed principally on the ground squirrel and woodchuck, which were considered to be the main reservoir hosts of the Rickettsia.

*Plague.*—Although the black rat (*R. rattus*) and its variants were the main reservoir host of plague, several other rodents might replace it. The ground-squirrel played an important part in California and in Southern Russia and Mongolia. The summer outbreaks of pneumonic plague in Mongolia and Manchuria corresponded with the hibernating habits of the ground-squirrels. In these regions the common house mouse was held responsible for winter outbreaks, though it was not incriminated elsewhere. In North China, Siberia, and Manchuria the Mongolian marmot was said to harbour the bacillus during hibernation and to cause outbreaks among the hunters, who lived huddled in underground hovels during autumn and winter. The musk-shrew and Bandicoot rat also played a part in plague propagation in India. Plague was first introduced into South Africa in 1901 and was then confined to domestic rats, but further outbreaks showed that the Cape hare, white-nosed rat, Cape jumping hare, and gerbilles were responsible for transmitting the infection. Carnivores preying on these rodents died of plague, and when the authorities found the remains of gerbilles in the fæces of sick mongooses and suricats, they took it as an indication that plague was endemic in that area. A shrew which lived in the houses in Senegal and West Africa was said to carry plague, and rabbits and hares had been found naturally infected in England.

*Tularæmia.*—This plague-like disease affected jack-rabbits, gophers, and other rodents in California, and was communicable to man, particularly field workers and dealers handling infected rodents.

*Melioidosis.*—This was a glanders-like disease of man occurring in Burma and the Malay States. The organism—*B. whitmori*—was a natural infection of the Malay rat, the local representative of *R. rattus.*

*Malaria.*—Strangely enough, human malarial parasites had never been found in any other vertebrate, although the great apes had their own species of plasmodium, from which it might be inferred that the original reservoir host of man's malaria was some extinct anthropoid. It was still a puzzle how these parasites with an intricate life-history became adapted to such dissimilar hosts. Possibly the blood protozoa of mammals were once parasitic in plants and became adapted to insects which fed on these plants, and thence to warm-blooded animals. Flagellates closely allied to Leishmania had been found in the latex of plants, and Migone had recently shown that a plant-bug was responsible for the spread of infection from plant to plant in Portugal. Morphologically, these and other flagellates inhabiting the intestine of house-flies, blue-bottles, and biting flies were indistinguishable from leishmania and trypanosomes.

Dr. Manson-Bahr illustrated his paper with numerous lantern slides and stuffed specimens of the animals mentioned.

### *Discussion.*

Dr. A. **BALFOUR** said that the problem of the origin of disease was insoluble, but the question of how human disease due to animal and vegetable parasites first began might be answered some day. The study of parasites responsible for certain plant and animal diseases suggested that the process of adaptation had been at work from the very earliest times. So far the only plant disease that could be called transmissible to man was the *Bacterium tumefaciens.* Recent research had not encouraged the idea that the leptospiral forms in insects were related to trypanosomes. It was curious that no reptile or bird had been incriminated in human disease; the only bird diseases conveyed to man were the psittacosis and aspergillosis of the domesticated parrot. It was most important to keep plague out of a country, for once it got in it was impossible to control these small rodents who might harbour it. Possibly we should find that wild animals played a greater part in the dissemination of disease than was yet known.

Dr. H. H. A. **SCOTT** mentioned rabies and the presence of *B. aertrycke* in some hamadryad baboons, causing acute intestinal infection; also that of the Morgan I. bacillus, which was associated with summer diarrhœa in infants, in some cercopitheque monkeys at the Zoo.

Dr. T. W. **CAMERON** referred to the helminth infections carried by wild animals, particularly the echinococcus, recently found in the wild fox. The parrot carried an organism probably identical with paratyphoid B, and all three forms of *B. tuberculosis.* The diphtheria said to be conveyed by wood pigeons and chickens was due to a totally different type of organism from the human bacillus, though the avian condition had caused a few cases of pseudo-diphtheria in children. Domestic ducks might harbour *B. aertyrcke.* Anthrax decimated the mammals of Africa: he asked whether it could be conveyed to man through eating infected flesh.

Major C. D. **DAVENPORT** asked what was the relationship between the dog, the bug, and Leishmania.

Dr. **MANSON-BAHR**, in reply, said that man was not subject to plant diseases because he had largely ceased eating raw vegetables. Ergotism was perhaps the only exception, except for the recent suggestion that beri-beri was not a deficiency disease but was due to eating rice infected by a fungus. Birds were so delicate and died so rapidly from any infection that they were not likely to convey disease to man. The rabies conveyed by wild animals was much more virulent than that of the dog, possibly because jackals and wolves lacerated the faces and heads of their victims. Anthrax was usually destroyed by the gastric juice and so was not conveyed by ingestion. The Mediterranean dog was susceptible to Leishmania and got something very like kala-azar, but the Indian dog did not, probably because the bug did not carry kala-azar and the sandfly did. In the Mediterranean area the dogs lived so close to man that the Phlebotomus transmitted the disease to both.

---

## MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

AT a meeting of this Society, held at the rooms of the Medical Society of London on Feb. 26th, with Dr. **WILFRID S. FOX**, the President, in the chair, a discussion on

SYPHILIS OF THE HEART AND AORTA

was opened by Sir **THOMAS HORDER**, who dealt especially with the early signs and symptoms of this condition.

The importance of the subject, said Sir Thomas Horder, rested on four basic facts. The first was that syphilis was a disease which was eminently amenable to treatment. The second was that in this, as in so many other disease processes, the success of treatment was in direct proportion to the early commencement of it. Thirdly, the tissues concerned were of vital importance, not only to health, but to life; and fourthly, if structural changes had set in before the disease was recognised, then, even though healing took place to a large extent, as it was known to do, the secondary changes in heart and aorta resulted in a limitation of activity, and even premature death. Hence the supreme importance of making every effort to diagnose and commence to treat the disease before these structural changes had set in. The post-mortem room evidence was that syphilitic disease of these structures was not rare; there was an incongruity between this evidence and that of clinical experience, in that the physician seldom satisfied himself that he was dealing with an early case of syphilitic disease of the aorta or of the heart. Thus it was a duty to be constantly on the lookout for the disease in practice, especially as it was very prone to be latent. One reason for this latency seemed to be that neither of the structures of the heart which yielded physical signs was often affected by syphilis—namely, the pericardium and the endocardium. All were familiar with cases of aortic incompetence which there seemed every reason to attribute to old syphilis. He sometimes drew attention to what he believed to be a parasyphilitic lesion of the mitral cusps, taking the form of mitral regurgitation, with a highly musical apical systolic bruit, of the kind one encountered in the routine examination of cases of tabes dorsalis. Also, there was a typical condition of heart-block when anatomical change had occurred in the bundle of His. But he did not propose to deal with parasyphilitic disease of the cardiovascular system, but rather to draw attention to the disease in its early and progressive stages, and afterwards to consider what was the appropriate treatment.

Sir Thomas Horder did not doubt that the thoracic aorta was more often attacked by syphilis in its early stages than was the heart itself, judging by the post-mortem data, the ascending part of the thoracic arch being the zone of attack *par excellence*. When the structures near the heart were involved by the disease there were two zones specially liable to attack—namely, the circle of Willis and its branches, and the base of the aorta and the part immediately above it. Between the primary infection and the invasion of these structures the period seemed to be about the same in each—namely, from five to ten years. He did not share the view held by some that it was not until later in the life-history of the disease that these structures were implicated. These manifestations were seen in people of 25 to 30, rather than from 30 to 40 years of age. All sorts of syphilitic developments occurred later in life, aneurysm a little later, aortic regurgitation later still. The doctor should be on the scene before these late sequelæ developed.

*Symptoms of Early Involvement of the Aorta.*—These, said Sir Thomas Horder, were largely problematical, and he was anxious by collaboration to agree on signs which would stand the test of experience. He could never feel quite certain of his diagnosis of syphilitic aortitis, but he insisted that the safe course was to treat the patient as a syphilitic suspect. He attached great importance to substernal pain, which he could reasonably attribute to the aorta, which was a very sensitive structure in a young man or woman. This anginoid pain was liable to be increased by effort, but was not necessarily induced by effort. One of the cases which he considered had this disease was sent to him as severe cardiospasm, the pain having been attributed to acid dyspepsia in a nervous subject. The speaker was not satisfied about the character of the aortic second sound; there was a clear history of infection seven years previously, and his blood gave a trebly-positive Wassermann, the Sigma reaction also being very definite. Anti-syphilitic treatment with prolonged rest brought about a complete cure. Pain he regarded as very important.

Less helpful because more vague subjective features were the following. First, a sense of oppression and discomfort in the chest, increased by effort; what could be expressed as an "aortic consciousness" as opposed to a "heart consciousness." Secondly, there was shortness of breath, but the number of conditions in which this was present reduced its diagnostic value. Added to this was a feeling of general physical slackness, coupled with some anæmia. Early physical signs of syphilitic aortitis were problematical. In none of the kind of patients under consideration could he satisfy himself that the aorta was dilated, though he was aware it had been reported, especially by the French, whose clinical picture of aortitis was much more elaborate than ours. Syphilitic mesaortitis was a patchy condition; and if it were so diffuse as to lead to dilatation of the aorta in a man aged 30 or 40, it would be so serious that the examination of it would probably be made in the *post-mortem* room. There was something helpful in the character of the sounds in these cases. In all cases in which there was substernal pain an aortic second sound should be carefully criticised. He considered that a blurring or lack of clearness in this sound should be seriously regarded, and it should be listened for also down the sternum and at the bottom of that bone. The late Sir William Osler spoke of the pulmonary base as "the area of auscultatory romance," but the speaker rather regarded this xiphoid region as the area of auscultatory neglect. Sometimes a definite and distinct aortic bruit could be heard there and nowhere else. A further suspicious feature was a sharply accentuated second sound in the absence of hyperpiesis, but he did not regard this as of equal importance to the last named. Collateral signs of syphilis were also very valuable, but they were not looked for unless the possibility of syphilis was in the examiner's mind. He referred to such conditions as leucoplakia, old scars, pigmentations, &c. And in a suspicious case the complement-fixation test would be tried. He did not regard the presence of an aortic diastolic bruit as a proof of permanent aortic incompetence.

*Early involvement of the heart* by syphilis was detected less commonly than in the case of syphilis of the aorta, partly because the important guide, pain, was absent in the heart cases. In hearts affected by syphilis there might be a sudden rupture of an aneurysm in the heart wall, or the production of an ischæmic infarct might result from endarteritis of branches of the coronary vessels. In regard to the heart in this connexion, he knew of only one suggestive feature—namely, the so-called heart-block syndrome. If that were present in any degree in a person under 50 there was always the hope that his syphilitic disease would respond to treatment.

*Treatment.*—On the subject of treatment Sir Thomas Horder said he had not much to offer. When it was proposed to treat a vascular lesion of supposed syphilitic origin he was often asked whether one should proceed slowly and vary the usual routine. The practice was to proceed with caution, though he was not aware of any real reason for doing so. Certainly there was great need to proceed as intensively as possible, short of inviting disaster. He had seen neo-kharsivan and such remedies given with much boldness, and had shivered for the result, but his anxiety had proved to have been misplaced. His own aim in these cases was to be very intensive and very prompt with mercury, giving iodide of potassium at the same time, and following this up by a routine series of doses of novarsenobillon, &c. Once having started treatment, he did *not* give these cases any smaller doses than he gave to any other syphilitic patients. He believed greatly in prolonged rest in the recumbent posture before starting therapeutic treatment.

### *Syphilitic Endocarditis.*

Dr. F. W. PRICE, who followed, dealt with the acquired form of the disease in the heart and aorta. Syphilis, he said, might attack the aorta, the cardiac valves, the coronary arteries, the myocardium, and the pericardium. Inflammation of the media of the vessels might be followed by necrosis of the elastic tissue and muscle-fibres, and, at a later period, by a new formation of fibrous tissue, thus bringing about a local weakening of the vessel, leading to aneurysm of almost any size. The thickening of the intima was a secondary protective or compensatory process. Fatty and calcareous degeneration was *not* present in the early stage of the disease. Secondary thickening of the intima had been erroneously confused with atheroma. The auriculo-ventricular bundle might be involved in the disease and cause heart-block. Syphilis of the pericardium was very rare. A histological diagnosis was very difficult, even in the early stage. He did not believe syphilis caused primary atheroma, but it was responsible for a large proportion of cases of aortic incompetence, and was an important factor in angina pectoris in patients under 40 years of age. Still, in the main, he considered that the part played by syphilis in the causation of diseases of the heart was over-stated. Dr. Price dealt fully with the symptoms and clinical signs of the disease in heart and aorta, and in the main agreed with Sir Thomas Horder. The prognosis, he said, depended largely on the stage at which the diagnosis was made, and on the kind of treatment adopted. Taking cases as a whole the prognosis was very unfavourable, perhaps largely because usually the diagnosis was not made until a late stage of the disease. The hope was that this defect would be increasingly remedied. In the absence of aortic incompetence the prognosis was more favourable. Prompt treatment sometimes prevented the more serious sequelæ. He agreed as to the great value of prolonged rest, and he did not regard signs of cardiac failure as a contra-indication to antisyphilitic treatment.

### *Discussion.*

The President agreed that, in the face of a positive diagnosis, there was no reason why cases of the kind being discussed should not be treated actively, especially as damage to heart and vessel walls was such a serious matter. He also referred to the diagnostic value of the provocative dose.

Dr. Strickland Goodall spoke of an experience of 220 cases of cardiovascular syphilis. When the myocardium was involved the signs produced depended on the part of that structure chiefly affected. If chiefly the auricle was damaged, auricular fibrillation was not uncommon; 14 of the 220 cases showed this. When the bundle of His was involved heart-block, either partial or complete, was produced. The electrocardiograph was very valuable in the diagnosis of myocarditis. In his 220 cases syphilitic pericarditis was present in only four. He was glad to hear Dr. Price say that in syphilitic aortic regurgitation there was not much ventricular hypertrophy, as it was a very important means of differentiation from other forms. He was glad also to hear of the faith still persisting in mercury and iodide of potassium.

Colonel L. W. Harrison said it was evident that by the time the physician was able to detect syphilis of the aorta or of the myocardium much damage had already been wrought by the disease. In the primary lesion the outstanding fact was the disease of blood-vessels, and the resultant fibrosis was the great enemy. Early treatment was directed to forestalling this crippling fibrosis. A statement frequently made was that it was unnecessary to treat a patient because of a persistently positive Wassermann if there were no symptoms, but the latency of cardiovascular syphilis and the difficulty of diagnosing it until serious damage had been done was a sufficient answer to those who took that attitude. With regard to treatment there was much difference of opinion as to the use of arsenical preparations, particularly in myocarditis, but he thought the arsenobenzol treatment had a definite place in the treatment of both myocarditis and aneurysm, though in the first of these care must be exercised. If small doses were commenced with and slowly increased there would be very little shock.

Sir Thomas Horder and Dr. Price replied.

Errata.—Dr. Knyvett Gordon points out that in the report of his remarks made at the discussion at the Medical Society of London on cholecystitis and published in The Lancet of Feb. 27th, p. 442, the words "Histological examination of the blood was of some value in the diagnosis *of gall-stones*" should have read "*of cholecystitis*," and "*the diastatic content of the urine* was also important" should have read "*the diastatic contents of the blood and urine.*"

## Reviews and Notices of Books.

### THE YOUNG DELINQUENT.

By Cyril Burt, M.A., D.Sc. Oxon., Professor of Education in the University of London; Psychologist in the Education Department of the London County Council. London: University of London Press, Ltd. 1925. Pp. 643. 17*s.* 6*d.*

Dr. Burt's position as an authoritative exponent of the psychology of childhood is already well established. This book, the first of a series of three dealing with mental abnormalities in the child, while nominally concerned only with the juvenile delinquent, might well serve as a text-book of psychology in general. The parts respectively played by intelligence, instincts, sentiments, and complexes in the determination of conduct are lucidly outlined and their abnormal developments illustrated by concrete cases of delinquency. From a psychological standpoint the book is more systematic than Dr. William Healy's Individual Delinquent, the only other comparable book on the subject, and one which has had much influence in America in stimulating the movement for the psychological examination of all delinquents. Dr. Healy's own work in Chicago and Boston soon found followers, and psychiatric clinics are now a recognised institution. In England it is still necessary to plead for them, and Dr. Burt's book may be regarded as an argument in their favour. In an appendix he describes the equipment necessary for such a clinic.

The work is an expression of the modern attitude to crime and the criminal. It is not so long since the criminal was looked upon as a degenerate human type, mentally and morally separated by a deep gulf from average humanity; he was born to crime and yet, by a curious paradox, regarded, if sane, by the law as responsible for his acts and a fit subject for punishment. In this book the criminal is seen as being of like passions with ourselves; the fundamental point of view is that "crime is a mental symptom with a mental origin," an origin usually multiple, and that until the origin is discovered there is no basis for suitable treatment, which must be primarily remedial and only secondarily punitive, the punishment fitting the criminal rather than the crime. In a series of fascinating chapters the author discusses, on the basis of observations of a large group of delinquents and a corresponding group of controls, the various causes he has discovered—hereditary, environmental, physical, intellectual, and temperamental—distinguishing also the most essential factor in each case from the less important contributory ones. The analysis is searching; the individual cases quoted give some idea of the care exercised in collecting and collating facts, in reaching a diagnosis and suggesting appropriate treatment. The readiness of magistrates to attribute all crime to picture-houses and pernicious literature might be effectively curbed by a perusal of the book; it might induce also an appropriate diffidence in dealing with such cases.

The rôle of heredity has, in Dr. Burt's opinion, been much exaggerated. "Contagion," he remarks, "is too often mistaken for heredity," and "the case of sporadic crime is more usual than the case with a criminal lineage." In between 60 and 65 per cent. of his cases the delinquencies were precipitated primarily by the difficulties of the environment or by personal history. In this connexion he has much to say of home discipline, and he points out the great difficulty an investigator has in obtaining a clear understanding of the home atmosphere, the emotional relations of its members to one another, and their reactions upon each other—factors often of supreme moment in delinquent cases. Sometimes, he adds, the offender is the most normal member of his group. But, whatever the external conditions that act upon the criminal, it is the reaction of his own mind to the conditions that determines the result; mental factors and particularly emotional factors count most.

Dr. Burt here reiterates his frequently-expressed opinion that the "moral imbecile" of the Mental Deficiency Act represents no true psychological entity, and pleads for the legal recognition of the "temperamentally defective." Expert opinion will now in the main agree with him. Treatment is discussed at very considerable length and with system. It should obviously begin early, before the habit of crime is established, must be adapted to the individual child, and also to the nature of the causes that provoked the crime. Special institutions designed for children of unstable constitution are urgently required.

This is a book to be read and re-read, and retained for reference by all interested in the moral welfare of young people.

### INHERITANCE OF CANCER

*Our Present Knowledge of Heredity.* Six Lectures under the Mayo Foundation, by W. E. CASTLE, C. E. MCCLUNG, J. A. DETLEFSEN, MAUD SLYE, H. G. WELLS, and M. F. GUYER. London and Philadelphia: W. B. Saunders Company. 1925. Pp. 250. 12*s*.

OF books on heredity there is no end, and these lectures given at various American universities under the auspices of the Mayo Foundation for Medical Education and Research would seem to be hardly worth a permanent presentation to medical men were it not for the inclusion among them of a statement by Miss Slye of the splendid mouse-breeding experiment which she has carried on at Chicago with such devotion for many years, and of a singularly comprehensive account of the inheritance of cancer from all its aspects by Prof. H. Gideon Wells, which incidentally has already appeared in the *Journal of the American Medical Association*.[1] The question whether cancer is heritable is one which disturbs the lay public more than it does the profession, who have settled that the practical importance of a cancerous ancestry is, to all appearances, negligible in man. Miss Slye concludes quite definitely—and supports her conclusion by the largest mass of accurate data which have ever been collected on the subject—that resistance to cancer is a unit character which is transmitted as a straightforward Mendelian dominant. Similarly the tendency to develop cancer is a unit Mendelian recessive which explains why it may remain hidden through several generations until the chance mating of the appropriate heterozygotes brings it out in a proportion of the children. Whether cancer actually develops or not in a homozygous recessive depends on the stimulus which the tissues receive. Taking as illustrative the example with which we are now familiar, the occurrence of cancer is the product of the heritable qualities of an organ in respect of cancer resistance and the irritation which it receives from outside. Miss Slye, by deliberate breeding, has produced strains of mice which nearly never or nearly always develop malignant tumours under the conditions of life which prevail in her mouse town. What happens when these two strains are, e.g., painted with tar seems to be unknown, but it has been ascertained that the children of rats in which cancer develops in relation to the liver cysts of *Tænia crassicollis* are much more prone than usual to respond in the same way to the presence of the parasite; in other words, the readiness with which irritation will cause cancer is shown to be heritable. The difficulty which arises from this relationship between inherited tendency and irritation is that it is hardly possible to regard the tendency as a single unit character if it is so variable, and Miss Slye frankly allows that some animals have it to a greater and some to a lesser degree and will require less and more irritation respectively to produce a frank cancer. Her main position is, however, not seriously affected if several factors are involved, and her account of her results deserves careful and attentive study by everyone who is interested in the third largest cause of death in this country. Prof. Wells's lecture covers a wider field, and gives an account of such human experience as is seriously germane to the question and of the results, homologous and analogous, of other investigators. His conclusion is that inherited tendency is one of the most important factors which determine the occurrence of malignant tumours. The last of the six lectures is on "eugenics," by Prof. Guyer; he does not venture to state what practical application should be made of Miss Slye's results. The truth probably is that something could be done if people felt keenly enough about it; and that it would not amount to very much. If the tendency to have cancer is a recessive character, most of the people who have it do not show any signs of it in their own persons; they cannot be killed, segregated, or even disliked, and indeed nothing may be known to their discredit till, long after they are dead, some of their children develop cancer. On the other hand, if Miss Slye and Prof. Wells are right, deliberately and productively to marry the child of cancerous parents is looking for trouble. As with mental deficiency, another Mendelian recessive, such selective breeding as is possible would have an effect, but it would not be large and would take a long time to show.

### DISEASES OF THE GUMS AND ORAL MUCOUS MEMBRANE.

Second edition. By Sir KENNETH GOADBY, K.B.E., Lecturer on Bacteriology of the Mouth, Dental Department, University College Hospital. London: Humphrey Milford, Oxford University Press. 1925. Pp. 408. 42*s*.

THE peculiar virtue of this book is that it is equally satisfying to the doctor and dentist. The former will find an adequate account of the pathology of what may be called the special dental diseases, not too technical though by no means superficial. To the latter the book is welcome for the account it gives of those rarer manifestations of disease in the mouth, the study of which hardly falls within the dental curriculum. The significance of dental disease in relation to the general health receives a detailed consideration, and the bacteriology of the mouth is clearly described. The general plan of the book has undergone no change, but certain additions have been made, notably a chapter on vaccine therapy and a section treating of the toxic heart in relation to dental sepsis. The method of injecting vaccines into the diseased area as advocated by Besredka is not mentioned, though it has received a wide publicity through its application to pyorrhœa by Goldenburg. It is surprising to find only a cursory reference to the root tumours so often found at the apices of dead teeth, for in the opinion of many observers this closed type of sepsis may be more harmful to the general health than the open lesions of pyorrhœa. The author apparently regards them as a form of chronic alveolar abscess, but their structure does not wholly support this view. Their pathology is admittedly obscure. It is quite possible that the radiographic appearance of apical rarefaction has received too great attention and may not warrant the sinister interpretation often placed upon it. A more detailed study of this aspect of dental infection both in regard to its bacteriology and its relation to systemic infection would be a valuable addition to the next edition of this work. No reference is made to the work of A. F. Hurst on achlorhydria and its bearing on pyorrhœa and systemic infection. Hurst's views, though still hypothetical, have so much clinical support that it becomes necessary to consider them in any account of dental disease as a factor in general disease. It is just in a book of this kind which is widely read both by the medical and dental professions that a full-dress study of focal infection in the mouth in relation to general disease would be specially valuable. The chapters on the special diseases of the mouth and gums, with excellent coloured plates, and on diseases with oral symptoms still remain the best sections of an admirable book.

SCOLIOSIS.

Rotary Lateral Curvature of the Spine. By SAMUEL KLEINBERG, M.D., F.A.C.S., Assistant Surgeon, New York Hospital for Ruptured and Crippled; Member of the American Orthopedic Association. New York: Paul B. Hoeber, Inc. 1926. With 140 illustrations. Pp. xvi. + 311. $6.

IT seems that with the best will in the world it is difficult to find anything new to say on this subject. Dr. Kleinberg has had good opportunities, of which he has well availed himself, of studying and treating scoliosis, and he has produced a sumptuous book, but he is able to bring forward little or nothing new on the pathology, ætiology, or treatment of this deformity, which in its worse forms is so distressing and so resistant to treatment. However, to those who would have in concise form a statement of what is known of this deformity and what measures can or should be taken to combat it, we recommend this book, which is illustrated by figures of great technical beauty and clarity. Dr. Kleinberg holds out no extravagant hopes of cure of structural scoliosis with bone deformity and his views on prognosis are sound and trustworthy.

## JOURNALS.

BRITISH JOURNAL OF OPHTHALMOLOGY. February, 1926.—This number contains two papers of clinical and pathological interest. The first is on Inflammatory Pseudo-tumours of the Orbit, by F. A. Williamson-Noble. Two examples of this somewhat uncommon condition are described, and also a third in which a blind eye was excised for a supposed intra-ocular tumour but in which no true tumour was discovered. In the first case, in which the proptosis was well marked but the vision good (6/12), the orbit was exenterated in the belief that a neoplasm was present. The condition found was a large gummatous mass surrounding the optic nerve within the muscular cone. This case should be compared with one reported by Mr. Lindsay Rea in which the proptosis was binocular but the Wassermann reaction positive, and which yielded to energetic antisyphilitic treatment.[1] In Mr. Williamson-Noble's second case the proptosis was also binocular, but in one eye became so marked that the probability of malignancy seemed so great that exenteration of the orbit was performed. Nothing was found except lymphocytic proliferation. It is suggested that the condition was due originally to infection by the blood stream from some distant focus, and that after the infection had subsided a mass of lymphocytes were left which continued to proliferate. (Mr. Richardson Cross published a binocular case in 1916 which he attributed to lymphoma.) In Mr. Williamson-Noble's third case there was no actual proptosis, but there was a condition found which, if left, would probably have caused proptosis. As a result of irritation induced by cholesterin crystals derived from an old intra-ocular hæmorrhage in an old blind eye, a small mass of young connective tissue was found outside the sclera after the eye had been excised. This is noted as a third possible explanation to account for some of these obscure cases of proptosis. Their clinical importance is great. No more difficult problem for the ophthalmic surgeon arises than whether or not to advise the sacrifice of an eye which retains useful vision on the ground of the possible but unproved presence of a malignant tumour.—The second paper is by J. A. Conway on Two Cases of Cerebral Aneurysm causing Ocular Symptoms, with Notes of other Cases. Aneurysm of a cerebral artery is seldom diagnosed but, it seems, is not so very rarely discovered on the post-mortem table. In the first case there was bitemporal hemianopia with some expansion of the sella turcica according to the X ray report, both symptoms pointing to the possibility of a pituitary tumour. Post mortem an aneurysm attached to the right middle cerebral artery was discovered. The aneurysm was old and completely filled with laminated clot. It occupied the sella, whilst the pituitary, normal in size and appearance, was lying behind it. An interesting point about this case is that before death the fields of vision which at one time had been hemianopic had almost recovered their normal size. Presumably this was due to the shrinking of the mass. In the second case an aneurysm occupied a considerable part of the cerebellum and caused optic neuritis so that a cerebellar tumour was simulated. With regard to the causation of these cerebral aneurysms Conway finds that in the majority of cases no sign of vascular or cardiac disease has been discovered, and concludes with Turnbull that in these cases the formation of a breach in the media is due to an inborn defect in the arterial wall.

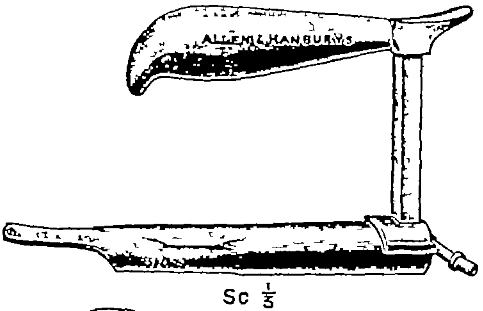
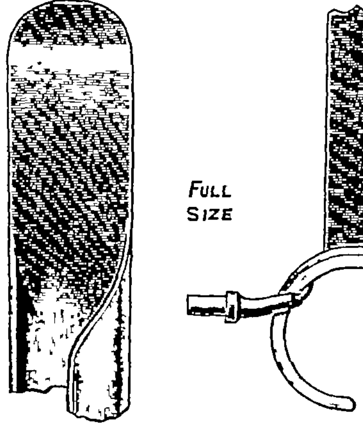
## AN IMPROVED LARYNGOSCOPE FOR ANÆSTHETISTS.

THE laryngoscope here illustrated, although conforming in general outline to other similar patterns, embodies certain features which have proved useful in passing catheters and their accompanying expiratory tubes through the larynx. These are: (1) efficient illumination from a lens-fronted electric bulb of the size usual in sigmoidoscopes; (2) the distal end of the speculum is flat, wide, and tilted slightly upwards—an advantage in elevating and controlling the epiglottis; (3) the unusual width of the slot at the side facilitates the passing of catheters and tubes for expiration without obscuring the visual field; (4) the lug at the proximal end of the handle affords a purchase for the thumb, which is of value in manipulating the instrument into position. The handle is not detachable, and the barrel, which is polished within as well as without, is constructed of stainless steel.





The instrument is supplied by Messrs. Allen and Hanburys, Ltd., of Wigmore-street, W. 1, and also by Messrs. Down Bros., of St. Thomas's-street, S.E. 1.

properly been given priority as the medical benefit under the Act has suffered throughout from limitations imposed by financial considerations and stated by the Commission to call urgently for removal. It would seem that, owing to the fact that sickness has cost less than was originally anticipated, there is a margin available out of present contributions, and the Commission expressly recommends that this margin should be applied to its full extent towards meeting the cost of extending the statutory benefits. The medical profession, as made clear by their evidence, are ready to coöperate with the Government in bringing into operation the extension of the scope of medical benefit which is contemplated. This extended service is not to be provided by way of development of the out-patient work of the hospitals, but through an independent scheme organised under the direction of the Ministry of Health through the whole country by the insurance committees or their successors as an integral part of medical benefit. Provision in the scheme should, it is recommended, be made for the closest coöperation between the general practitioners and the specialists, particularly for the exchange of information as to cases, and for the giving of definite guidance to the general practitioner as to both diagnosis and treatment. Any practitioner possessing the requisite qualifications should be entitled to take part in the work, and the decision as to whether particular practitioners possess these qualifications would lie in the hands of a mixed lay and medical committee for each area. It will be observed with interest that ophthalmic benefit would be recognised as part of the expert out-patient service under the scheme, and would be available only on the recommendation of the general practitioner. The second recommendation in order of priority is for the provision of allowances in respect of dependants of insured persons in receipt of sickness or disablement benefit. This takes the form of a small addition to the worker's own sick benefit, and must not be confused with any extension of medical benefit to dependants, which, as we some time ago indicated, is not in the region of practical politics. There will be general agreement with the next recommendation that there should be an improved provision at the time of pregnancy and childbirth for insured women and the wives of insured men. As soon as funds are available, the scope of maternity benefit should, it is said, be expanded to cover medical and midwifery services in addition to a cash payment; the service element should then be administered by the local health authorities and coördinated with the other local medical services, and a cash element would be retained and be administered in connexion with other cash benefits.

The Commission gives its blessing to a complete dental service available to the whole insured population as an eminently desirable addition to the insurance scheme, and our readers will remember that there has throughout the evidence been an insistent demand for such a service and a readiness on the part of approved societies to anticipate future surpluses by ear-marking part of the contributions for a statutory dental benefit. This, however, has been found to be financially impracticable at present, and is placed fourth in order of priority. The existing arrangements whereby dental benefit is one of the additional benefits administered by the societies out of their
rpluses will continue, subject to an important pro-
on that the organisation and supervision of the
ice should rest with the central department, and
n interesting proposal that a regional dental

by them. In regard to the additional benefits generally, in spite of their unequal distribution and the lack of uniformity in their administration, it is not considered that there should be any change at the present time, but that the approved societies should continue as heretofore to administer these benefits. Some mitigation of the inequalities should, it is thought, be effected by the partial pooling of surpluses on lines indicated in the report. The approved society system stands firm for the present in regard to cash benefits generally, but it is foreshadowed that their position might have to be reconsidered in the event of fundamental changes being made in the system of social insurance. As was generally anticipated, it is recommended that insurance committees should be abolished, and their powers and duties transferred to committees of the appropriate local authorities, such committees to contain possibly a proportion of coöpted members; while a pious hope is expressed that regard should always be had, in any developments of the insurance medical service, to the importance of the fullest possible coördination with other health services. The general question of coördination, being a very wide one, is not unfairly regarded as outside the scope of this Commission's deliberations.

The principal recommendation which emerges—the extension of the scope of medical benefit—will, we hope, be capable of immediate realisation, and the Minister of Health may be expected, in closest consultation with the representatives of the profession, to give effect to this recommendation, and so make good what has always been recognised as a serious defect in the medical benefit provisions of the National Health Insurance Acts. So much we feel justified in anticipating.

## MORVAN'S DISEASE.

THE history of the disease, or more properly speaking the syndrome to which the name of MORVAN is attached, is a fine illustration of the advances in medical knowledge which may follow the astute observations of those engaged in general practice. It is proper that consulting physicians should acknowledge the debt that we all owe to such observers, and Prof. C. ACHARD, in the latest volume [1] of the Clinics of the Hôpital Beaujon, has seen fit to devote the first of an absorbing series of essays to the story of MORVAN'S discovery. In 1883 Dr. MORVAN, a general practitioner of Lannilis in Brittany, published an account of seven cases of which the outstanding clinical feature had been the occurrence of recurrent painless whitlows appearing on both hands. He stressed the symmetrical nature of the lesions, noted their occasional occurrence in the lower extremities, and formulated the hypothesis that the anatomical site of the primary disease lay in the cervical portion of the spinal cord. His observations had extended over a period of 30 years. The discovery was followed by isolated reports of similar examples of this phenomenon, and three years later, in a second memoir, MORVAN reported eight further cases, giving a description of the painless arthropathies sometimes accompanying the disease and of the scoliosis which was usually present. During the following three or four years the pathology of the disease remained entirely obscure; autopsies on cases had not been performed, or rather the rare autopsies had been conducted in circumstances which did not allow of immediate examination of the nervous tissues, and whilst some neurologists, by a process of deduction, held that syringomyelia was the essential cause of the disease, others, basing their views on the rare sections of nerves which had been seen, believed the disease to be of the nature of a peripheral neuritis. At last a complete post-mortem examination of a case of Morvan's disease, dying in the Salpêtrière, disclosed a typical state of syringomyelia, so that the majority of French neurologists, headed by CHARCOT, were convinced that this was but a clinical type of the latter malady. The interest of the lay public in France in matters concerning medicine and pathology is well illustrated by the fact that in 1893 MARCEL PRÉVOST published a novel entitled L'Automne d'une Femme, containing a full description of Morvan's disease and attributing its origin to syringomyelia. Meanwhile there remained certain adherents to the theory that neuritis rather than an intraspinal lesion was the primary disease. DEJERINE particularly clung to this, and drawing attention to the frequency of occurrence in a circumscribed area in Brittany, suggested the probability of an infective neuritis analogous to that seen in leprosy; but the controversy was rendered even more bitter by the intervention of ZAMBACO Pasha of Constantinople, an acknowledged authority on leprosy, who maintained that both Morvan's disease and syringomyelia were nothing more or less than manifestations of that dreaded infection. This opinion has not been upheld by subsequent experience; to-day it is agreed that the essential lesions of leprosy are found in the peripheral nerves, and that the excess of neuroglia with cavity formation in the cord is not found in that disease. And it is further held, by those best qualified to judge from a wide experience, that Morvan's disease is but a syndrome, whose painless whitlows are the expression of syringomyelia in nearly all cases, but that in rare cases leprosy affecting the peripheral nerves has been its cause.

## IRREGULAR MEDICAL PRACTICE.

ON Monday last Lord DAWSON OF PENN addressed a meeting of both Houses of Parliament on the subject of medical practice by the unqualified, and a summary of his words and of the discussion which arose thereon will be found in another column. Open debate free from animus between the public and the medical profession ought to make plain that scientific medicine is not afraid of competition, and various Members of both Houses of Parliament put questions to Lord DAWSON, the answers to which must have considerably cleared away general misunderstandings, and should lead to a wiser spirit of criticism. The acrimony which has marked recent strictures of the medical profession should cease to be displayed by reasonable people, appreciating that the policy of the profession is conducted by its members with the utmost desire for the public weal, and is regulated by Acts of Parliament having no other object.

Of all the lessons which Lord DAWSON was able to draw from his experience as clinician and teacher, none probably will be more useful to the public than his insistence that education and training along a standardised course must precede any attempt to solve the problems of medicine. This fact is not only made patent by the Medical Acts, where such a course is laid down as necessary for the equipment of all medical men in order that the public may be protected from the perils of untested pretensions, but it is recognised also within the course itself, where two-thirds of the time which is compulsorily expended in medical education and training is consumed in the acquisition by the students of fundamental scientific knowledge and comprehension of general principles, only a third of the curriculum being devoted to learning the methods of treatment in their application to the sick. This is only another way of stating the truism that while upon diagnosis depends all that is trustworthy in medical practice, the power of diagnosis can come only to those who have built their education upon sound foundations. The therapeutic developments of the present, with their remarkable promise, and the hard-won wisdom of the past, are stultified alike if the patient is not submitted to the general and particular scrutiny which those who have been fully trained can provide—and no others. Treatment must bulk most largely in the public eye; the patient desires to be treated and is not concerned in making inquiries into the academic equipment of his doctor. To a certain extent he can judge of treatment by its results, and to a certain extent he will be, and should be, influenced by the statements of doctors in regard to ability to deal with the condition. But it is a fact that many a condition appears to improve under very varying procedures, and the man without qualifications, one of what the Minister of Health termed "the irregular army," unable to produce any other evidence of his knowledge, must depend for public support mainly upon the assertion of his successes, and there is no scientific ground for approval of his methods and no real proof that they have been fortunate to the extent claimed. For these practitioners we have seen support claimed on the ground that they are concentrating their mental powers, whose sharpness, it is stated, has never been blunted by the accumulation of irrelevant knowledge, upon the one thing that matters—namely, treatment—and the public have lost sight of the fallacy in the argument, so much is treatment the thing with which they are concerned. Treatment can only be administered logically in proportion as the cause of the condition has been ascertained, and the only way to wrest from medical science the capacity for diagnosis is through submission to an arduous course of training. As Lord DAWSON said, "wonder-working short cuts" should be distrusted, and so should the independent diagnoses of those who are not properly equipped. The therapeutic methods of these may often be useful, but their diagnoses are simply dangerous.

**JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.**—The Schick test was the subject of a paper by Dr. Matthew Fyfe, medical officer of health for St. Andrews and clinical pathologist to the Institute. After a reference to the incidence and death-rate of diphtheria and to the expenditure incurred by isolation and treatment, Dr. Fyfe gave a description of the Schick test. By its use during an epidemic it was possible to detect susceptible contacts who could then be temporarily immunised by antitoxin. When time permitted toxoid antitoxin could be employed to produce a more lasting immunity. He described the passive immunity, apparently derived from the mother, of newborn infants, the gradual loss of this in the first two years of life, and the gradual development of acquired immunity after puberty, and emphasised the high incidence and death-rate of diphtheria from the second to the tenth years of life. The value of the Schick test as a check on vague bacteriological reports and as an aid in the identification of carriers was illustrated, and its simplicity, cheapness, and safety were emphasised. In conclusion, Dr. Fyfe referred to the results of immunisation of Schick-positive subjects in Great Britain and elsewhere. He looked forward to a time when by a general adoption of these methods diphtheria would be banished from the list of common diseases dangerous to life.

"Ne quid nimis."

## THE POLLUTION OF STREAMS.

To a recent number of the "Public Health Reports,"[1] issued weekly by the United States Public Health Service, Surgeon W. H. Frost contributed an interesting review of the work done by the service on stream pollution. The first systematic research on the effects of sewage pollution in a large area was made in 1910 by Surgeon A. J. McLaughlin; but it was not until 1913 that the services of engineers, chemists, biologists, and bacteriologists were enlisted in carrying out a concerted plan of investigation. Between that year and 1917, when America entered the war, a good deal of work was undertaken, notably on the biochemistry of sewage, the treatment of industrial waste, and the effects of natural purification in inland and tidal rivers. In 1920 the undertaking was resumed, and a survey was made of municipal methods of sewage disposal and of arrangements for water purification in a number of cities on the Ohio River and elsewhere. The object of this last investigation was mainly to ascertain the exact relations between pollution of raw water and the quality of effluent obtained under varying processes and conditions of treatment. In addition to this a good deal of laboratory work has been done during the last few years. In Cincinnati various investigations have been made, including an attempt—so far not very successful—to reproduce on a small scale the phenomena of bacterial purification as they are seen in small streams. The biological oxygen demand of sewage, of industrial waste, and of polluted river waters has been studied carefully, and experimental research on the relation of pollution to the quality of effluent has been carried out in extension of the field work done on the efficiency of municipal filter plant; experimental sand filtration plant was designed so that the conditions of loading and of operation could be varied at will through a wide range. Research on the phenomena of bacterial purification has incidentally involved rather extensive study of the biology of plankton, and other useful theoretical work has been done by Dr. William Mansfield Clark, of the Hygienic Laboratory, who has been working for several years on the physical chemistry of coagulation in so far as it bears on the purification of water. In a general review of the subject Surgeon Frost points out that the resources at present available are inadequate to cover the many fields of work which claim attention. Even now 85–90 per cent. of sewage in the United States is discharged without treatment into convenient streams; though, as he hints, there seems little justification for this state of affairs now that the best means of purifying sewage are fairly established. Surgeon Frost does not, however, consider that the risk of local authorities drawing their water from polluted streams justifies intervention by the public health service, for the purification methods at present known are capable of dealing with the pollution. In his forecast of future developments he seems, while he admits the complexity of the subject, to be employing the work and recommendations of our own Royal Commission on Sewage Disposal. It hardly appears that he is fully conversant with their results, for he remarks:

> "Unfortunately, sanitary science has not furnished such full and precise knowledge as will be required on any of these points, especially in regard to the natural agencies which tend so greatly and rapidly to reduce bacterial contamination and which constitute one of the main reliances for protection of health. Moreover, it seems unlikely that it will be possible to borrow this knowledge from the experience of other more densely populated countries, as the writer knows of no other country having similar problems in the control of stream pollution on a comparable scale and for a similar purpose; that will probably have to be studied successfully before a solution becomes necessary for some of the great river systems in the United States."

---

[1] Public Health Reports, Jan. 15th, 1926, vol. xli., No. 3.

In making these comments he does not seem to have taken full account of the work of Boyce on the Severn and Houston on the Thames, or of the investigations of Adeney on oxidation, of McGowan on aeration tests, of Fowler, Ardern and Haworth on bio-aeration of sewage, or of the progress made by the Conservancy Boards during the last 30 years. Also he seems to have forgotten that the Royal Commission, having arrived tentatively at certain standards for sewage effluents, tested their practical value all over the country, in rivers with all degrees of pollution and dilution. The observations, it will be remembered, included topographical notes on apparent nuisance (smell, foul deposits, fungoid growths, and the like), and involved numerous chemical, biological, and bacteriological investigations. The West Riding Rivers Conservancy Board, although dealing almost exclusively with non-drinking water streams, has, during the last 30 years or more, contributed so much to the general store of knowledge of river pollution that all countries might well feel that their own problems were simplified, and other good spade-work has been done by the neighbouring Mersey and Irwell and Ribble Joint Committee Boards. Be that as it may, we fully appreciate the excellent work carried out by the Public Health Service of the United States. It has proved of signal value in connexion with our own pressing problems of pollution and purification, and will certainly be of like value in the future.

## CLEAN FOOD.

A joint committee of the Royal Sanitary Institute and the Society of Medical Officers of Health have just issued their report[1] on the question of food handling in this country. The method adopted by the committee was to depute the investigations of various branches of the subject to individual members of the committee, and the report now published contains an account of these individual investigations and the general conclusions of the committee thereon. The committee are greatly impressed by the fact that Great Britain alone among the more advanced nations has failed to take cognisance of the existence of risks to health from careless handling of food, and to provide legislation for the protection of the people from such risk. This fact is well brought out by the epitome of food legislation and regulations in other countries prepared by Dr. Francis J. Allan. The difficulties in the way of producing direct evidence of injury to health from the careless handling of food are emphasised, but there will be, we think, general agreement with the findings of the committee that there are sufficient grounds on the plea of cleanliness and decency, and probably of disease prevention, for devoting much greater attention to these matters. It may be true that the majority of the people are apathetic, but it is also true that there is an increasing body of public opinion which demands the exercise of greater care. The committee urge that all food premises should be registered with the local authority, and that no premises shall be occupied for any purpose connected with the preparation, storage, or sale of food until they have been so registered. The final report of the Departmental Committee on the Use of Preservatives is quoted in favour of further control of methods of food preparation. Some progress has been made with regard to milk, and the meat regulations which came into force on April 1st, 1925, have already raised the standard of meat purveying. There is much greater reason, however, for regulations with regard to other foods, especially those which are consumed uncooked, than there was in the case of meat. The efforts made in America to eliminate from the food trade persons who are capable of carrying diseases are quoted with approval in the report. The joint committee placed their views before the Minister of Health on Nov. 16th, 1925, the procedure which they recommend being first of all registration, and in the second place regulation. It is suggested that one set of regulations might deal with principles of common application to most foodstuffs and that separate regulations might be made for special foods. The committee recommend that local authorities should have power to make by-laws subject to the approval of the central authority, and that the central authority should issue model by-laws for the guidance of local authorities. This question of care in the handling of food is intimately connected with that of the use of preservatives and the enlightenment of the public as to what they are purchasing. We have hitherto depended far too much upon the principle of *caveat emptor*. As the report points out again and again, education of the public and of the trades concerned is a necessary preliminary to progress.

## SOCIAL HYGIENE: THE IMPERIAL ASPECT.

Recent reports by Government officials and representatives of voluntary organisations go to show that the problem of venereal disease within the Empire is a very serious one which has been largely left untouched. Thus the Mandates Commission of the League of Nations has recently drawn attention to the prevalence and apparent increase of venereal disease among the native populations of the African Mandated Territories. The East African Commission has pointed out that everywhere in that part of the world the infantile mortality-rate is grievously high, "being due mainly to venereal disease, ignorance of child welfare, and tribal customs." In the district of Bunyore, in Uganda, for example, it is estimated that practically the whole population is syphilitic. In the Wood report on conditions in the West Indies it is stated that venereal diseases are rife and that very little headway has yet been made against their further spread, while in many of our Far Eastern possessions and colonial seaports the prevalence of venereal disease is a matter of grave concern to the medical services of the navy and mercantile marine. In certain places the solution of the problem is largely bound up with the provision of an adequate medical service. In Nyasaland, for example, the total European medical staff amounts to 14, which leaves a working total of 10 or 11, and these have to deal with a native population of nearly two millions. The principal medical officer of the Tanganyika Territory estimates that less than one-twenty-fifth of the population is within the sphere of medical influence. The problem of providing an adequate medical service appears to be largely a financial one, and under the scheme for the East African Development Loan, shortly to come before Parliament, it is recommended that a certain proportion be allocated for the medical services. Unfortunately, it appears from certain official pronouncements that this may all be used for endowing certain institutions for scientific research. With regard to venereal disease, enough is known to permit of very satisfactory measures of diagnosis and treatment, and it is adequate medical services rather than further research which is necessary if this Empire problem is to be solved. That this is so is shown in the case of Uganda, where, five years ago, the population was falling, largely owing to the prevalence of venereal disease. With increased expenditure in general health measures, including £22,000 for antivenereal work in 1923, this fall has been checked and the health of the tribes in the area has been sensibly improved. The spread of venereal disease in Hong-Kong and Singapore has been brought under control to a certain extent by the comparatively recent provision of facilities for free treatment, but it also appears necessary that all known centres of prostitution should be eliminated. In many of the ports of the China station, according to Surgeon-Commander T. B. Shaw, speaking at the Imperial Social Hygiene Congress at Wembley, promiscuous sexual intercourse is "made more easy by the presence of regulated or tolerated brothels." Thus the venereal disease problem in the Empire affects not only the native populations but also visiting members of the navy and mercantile marine. From the economic point of view the virility and efficiency of the native races is of prime importance to the development and maintenance of the Empire, while the dangers of prevalent disease among a shifting population as represented by seamen is too obvious to require emphasis. From a financial point of view, again, to put it no higher, any expenditure on combating venereal disease within the Empire will certainly be money well spent.

## BURNS FROM A NEW POINT OF VIEW.[1]

THIS is not a disquisition on a painful group of injuries, but a study of Scotland's greatest poet—a reprint of a series of articles originally published in the *Glasgow Herald* with the object of rehabilitating the memory of Burns which, according to Sir James Crichton Browne, has been smirched by his biographers. The popular estimate of Burns is that he was a genius from peasant stock who wrote lyrics of surpassing beauty but who died at the early age of 37 worn out by drink and debauchery. The former portion of the estimate is true, but the latter portion, according to Burns's latest learned biographer, is entirely erroneous and is mainly due to the life written by Currie, "the arch calumniator," who was a fanatical teetotaller and could not forgive Burns's frequent allusions to wine and women, nor his somewhat latitudinarian views on religion. No doubt the popular estimate of Burns as a drink-sodden debauchee is wrong, but we think that Sir James Crichton-Browne makes too little of his failings, which failings he certainly did not minimise himself. The author considers that Burns's death was due to an exacerbation of the chronic endocarditis from which he had probably suffered from his early days, but even he allows that "an injudicious use of alcohol may have hastened its progress." Many people in the eighteenth century drank too much, and it is not surprising if Burns did so also, but the many allusions to drink in his verse and letters do not necessarily mean that he was a drunkard, any more than the similar passages in Anacreon or Herrick mean that they exceeded. Burns is, anyhow, too firmly enshrined in the hearts of millions to have his fame diminished by the failures and irregularities which are common to all of us, and, more especially, it seems, to the creative artist.

## HEALTH OF THE U.S. NAVY AND ARMY IN 1924.

THERE were 119,000 men in the Navy of the United States in 1924—the total figure is not definitely stated but can be arrived at from percentages which are based upon figures. This force had, per 1000, 496 admissions for disease, 61 for accident, 557 in all. The death-rates were, for disease, 1·78, for accident, 2·39, total 4·18. The most frequent cause for admission was gonorrhœa, with tonsillitis second. Tubercle caused 237 admissions, more cases than there were in the smaller British Navy in 1922, the last year of which we have yet been told, but fewer per 1000, 2·00 against 2·26. Dysentery cases are divided, as they should be, into bacillary (1·15 per 1000), and amœbic (0·31), in all 1·46. Stress is being definitely laid on keeping personnel fit and preventing invaliding. There are 824 medical officers, which is 1 to 144 personnel, but there is no statement of the number of associated civilians for whom they have also to care, such as is given for the Army.

In the Army of the United States in 1924 there were 136,485 men, and the Medical Department had under its charge another 75,000 civilians, as well as many pensioners. In the Army there were, per 1000, 335 admissions for disease, 121 for injury, 456 in all. The deaths were, from disease, 1·94, from injury, 1·89, in all 3·83. The chief causes of death were, in order, suicide, tuberculosis, automobiles, and airplane accidents. These last are becoming less frequent, and the flying hours per death have increased in four years from 955 to 3365. The leading cause of non-effectiveness was venereal disease, but the rate has been reduced by two thirds since 1908 when the preventive campaign was inaugurated. The Army daily appreciates more highly the work of the Dental Corps. It is the Veterinary Corps, a corps within the Army Medical Department, that examines meat, dairy products, &c., before acceptance. This inspection, saving the Army from buying bad food and forage, is thought to prevent a waste of money annually greater than the whole cost of the Veterinary Corps, which thus, it is supposed, pays for itself on a side issue.

The Surgeons-General of the Army and Navy of the United States follow a commendable routine in publishing simultaneously the statistical data of the year within a twelvemonth of its expiry. Their reports are abstracted in the *Military Surgeon* for January on which we have here drawn. Both services have increased their medical personnel by accepting on graduation senior medical students, who join the service hospitals as interns on the full pay of first lieutenants. They have the opportunity a year later, if approved, of joining their service, and in fact many of them do so.

## SPECIFIC FACTORS AND ANTITOXIN PRODUCTION.

IN the effort to produce therapeutic antitoxins of high specific value two lines of approach to the problem are open. On the one hand, we have the attempts, which are constantly made, to find types of antigen especially suitable for this purpose, and to ascertain the route, dose, and time of injection which will yield the most favourable results. On the other hand are the endeavours to modify the wholly unknown mechanism by which antitoxins are produced and to augment the output. Such endeavours have been, as a rule, empirical, although sometimes successful, and G. Ramon[1] has recorded the most recent of these. His attention was arrested by the fact that amongst a series of animals used for the production of diphtheria antitoxin, the concentration of this did not in all cases fall off after the bleedings had been initiated. As a rule the curve of antitoxin concentration in the animal's blood, having reached its highest point, thereafter progressively falls. In some cases Ramon found the fall to be checked and an augmentation to occur which occasionally was considerable. Investigating the matter further he found that the animals which behaved in this way were the ones which developed abscesses at the site of inoculation due to skin infection. He further was able to show that such augmentation in the antitoxic value of the animal's serum only occurred when the abscess was at the site of inoculation of the serum and not if it were elsewhere. Moreover, a quasi-chronic infection was more effective than an acute one associated with much constitutional disturbance. The investigator proceeded to reproduce the natural phenomenon experimentally in the endeavour to achieve a useful increase in the antitoxin of his sera and, after essaying various non-bacterial irritants, he found that starch, in the form of semolina, introduced along with the toxin or anatoxin with which the animal was injected, produced a local inflammatory reaction of the type desired. In experiments which are quoted upon diphtheria antitoxin production, the horses subjected to this procedure gave a yield of toxin which was approximately double that of animals hyper-immunised in the usual way, whilst in the case of tetanus the antitoxin yield by the new technique was as much as ten times that obtained from control animals. These observations are of importance as well as of practical interest to those engaged in the commercial production of antitoxin, whilst on the other hand they may be extended to throw some light upon the obscure question of the mechanism of the process.

## NEW PENSIONS REGULATIONS.

THE National Health Insurance Joint Committee, in conjunction with the Treasury, have published draft regulations which, although they do not take effect until 1928, are of immediate interest to large numbers who may contemplate becoming voluntary contributors under the combined scheme of health insurance and contributory pensions. The persons mainly concerned are those engaged in certain "excepted employments" under the Crown, public authorities, railway companies, &c., who pay contributions at a reduced rate for widows' and orphans' pensions only or who would pay these contributions if their remuneration did not exceed £250 a year. They are not insured for old age pensions under the Contributory Pensions Act, because they are already provided for in this respect by the terms of their employment, and they cannot qualify for these pensions in addition to their superannuation allowances by becoming voluntary contributors (if qualified), or taking up insurable employment, except so far as may be provided by regulation. The effect of the regulations now published is to enable those who are under 45 on becoming voluntary contributors or employed contributors, and also those who have already been insured under the health insurance scheme from some date prior to the passing of the Pensions Act, to qualify on the usual terms for pensions at 65 at the full rate of 10*s.* a week. As to the remainder, the rate of pension payable, if and when they retire on superannuation will be scaled down according to their age at last entry into full insurance —viz., 9*s.* a week where the age was 45 or 46 at entry, 8*s.* where the age was 47 or 48, and so on, down to 2*s.* where the age was 59; and where the person was 60 or over at entry no old age pension will be payable. Persons who have already retired from employment of the kind mentioned above will be subject to the same regulations. Somewhat similar provisions will apply to exempt persons over 45 who surrender their exemption certificates and become insured, as well as to men over 45 who become voluntary contributors on the ground of previous employment if they held exemption certificates when employed.

## STATUS LYMPHATICUS: AN INVESTIGATION.

AUTHORITIES have long differed on the importance, the frequency, and even the existence of status lymphaticus, and the Medical Research Council and the Pathological Society of Great Britain and Ireland may count on the willing coöperation of the profession in their attempt to throw light on the subject. Such an attempt is not, of course, new. An investigation was begun in 1914 but the work was interrupted by the war, and the death of the organiser, Prof. Emrys Roberts of Cardiff, was a further blow to the undertaking. A short interim report was eventually published,[1] but the material was too scanty to permit of authoritative conclusions, and the present scheme aims at collecting a much larger mass of information. The committee that has been formed has 15 members, nearly all of whom are professors of pathology in universities throughout Great Britain, and the scheme includes the appointment of investigators in large centres who will collect detailed records. This, however, will only be a part of the work, and all pathologists and others who make post-mortem examinations are earnestly invited to coöperate. The special objects of the investigation at present are:—

1. To establish, by means of a large series of weights and measurements, the standards of weight for age and proportion to body-weight of the normal thymus at all ages.
2. To investigate closely the precise cause of death in persons dying suddenly from unexplained and trivial causes, where the only apparent abnormality is the presence of a large thymus.

The committee wants the appropriate information for all cases of sudden death in apparently healthy persons, including deaths from accident, and for all cases of death in persons of 15 years or over who have an apparently glandular thymus. Not all workers, of course, have time to make very elaborate investigations, and two kinds of record card have therefore been prepared, one of them for the special investigator and the other for the busy worker who would like to help the committee as far as he can but is unable to do more than give a brief account of his cases. It is hoped that a great many practitioners will use the cards. Application for them should be made to the secretary of the committee, Dr. Howel Evans, Pathological Department, University of Liverpool.

## HYGIENE ON THE SEA.

ACCOMMODATION for seamen in ships of to-day is well illustrated in the *Asturias*, the new liner built by the Royal Mail Steam Packet Company for the South American passenger and emigrant trade to Brazil and the River Plate. The successor to the well-known hospital ship of the same name, torpedoed in the war, is the largest motor ship afloat. A special correspondent of THE LANCET was allowed by the Company to visit her before she sailed on her first voyage, and though opportunity was not forthcoming to ascertain the important particulars concerning ventilation, inspection showed the general advances made. Our correspondent writes:—

"Motor engines take up much less room than the old pattern, especially as there is no need for a boiler room, and the increased space available for crew and passengers is at once apparent, rooms and passages being nowhere less than ten feet high, constituting a vast improvement in comfort and making for health.

"The *Asturias* is a ship of 35,390 tons, 630 ft. long, 78 ft. broad, and her engines of 10,400 horse-power, working on two screws, drive her at 17½ knots. She has a crew of 465 all told, and carries 1324 passengers, 100 first-class, 250 second, and 674 third. Every compartment has supply and exhaust artificial ventilation, is heated by electric radiators, and has, it appears, one or more electric fans. All drinking water is filtered, probably by Chamberland-Pasteur candles. The stewards and crew are berthed in cabins giving them over the regulation 120 cub. ft. of space per man. There may be 12 beds together, but there are generally fewer; the beds are good, on iron standards, never, if I am right, against the ship's side, so they will not be wetted by condensation, as was once usual; besides there was cork paint—good cork paint and put on thick—to protect against the cold of winter. The lavatories in these sections are commodious but have only cold water laid on. There are full-sized baths in each section, and the water-closets are pedestal with a good flush, each in a separate compartment of sufficient size, and in each a fitting to take a roll of paper which we can hope will be provided. It is a pity that all the closets are not painted white, which shows up dirt so much more insistently. There are mess-rooms for each group of the crew. The stewards' accommodation is familiarly known on board ships as the 'gloryhole,' and one of the stewards here, being asked, said he had never seen a better 'gloryhole,' and he was probably right. Though a mess-room is provided for them, pressure of work sometimes compels them to take their dinners standing outside the pantry in the old, bad way; discipline would prevent this, and anyway, that area in this ship is airier and cooler than in most. Third-class passengers are berthed forward, and have a good saloon with the usual annexes; they sleep either on a troop-deck, with never more than four beds together, or in four-berth cabins, each with a folding wash-place, and water in cans. In all the passages are drinking taps with constant iced water-supply. The second-class cabins are aft; hot water is supplied to their basins. For the first-class there are the large and lofty saloon, numerous lounges, two libraries, a spacious verandah café, a smoking room, a large swimming bath, beautiful with white tiles and red walls, and the two promenade decks. The lower of these is some 13 ft. high, the upper is shut in with windows if desired, and higher still there is a belvedere. With all these chances of variety there should be no boredom on the voyage. There is a delightful nursery, with castle, swings, and other delights to keep the small children good tempered.

"There are two dispensaries, one with English, one with Spanish medicines. There are three hospitals, one, quite small, for the crew; one for infectious cases on the boat deck, with four beds for men in one section, four for women in another. On the main deck below is an extensive medical establishment, an inspection room with steriliser, hand-lamp, and other perquisites, the dispensary, a well-lighted and ventilated padded room, a men's hospital of ten beds, an operating room, a maternity ward of two beds, a women's hospital of eight beds, and a dining-room for convalescent patients. There is a Clayton apparatus for sulphur fumigation, also a steam disinfector, and the ship has an electric laundry.

---

[1] Journal of Pathology and Bacteriology, April, 1925.

"Great attention has been paid to the kitchen arrangements. Each group, crew, third-, second- or first-class passengers, has its own galley or kitchen, and its bakery. Except for the stock pots and the steaming of vegetables all cooking is done by electricity, and in each bakery there is an electric dough-mixer. The crew's galley marked, I thought, a great advance; it was so much better ventilated, so much more comfortable than another I recalled in a ship of this line some ten years ago. But it has still to be tested in the tropics."

It will be apparent from this report that the coming of the motor-ship has disarranged all the old ideas about the practice of ventilation in ships, whatever the mechanical details or structural technique. No longer is there a great hot mass of metal, water, and air extending three-quarters of the length of the ship, heating her up and all the air inside her as well, prepared to cause motion, that is ventilation, if escapes were provided, but to give trouble if they were not. It is a great satisfaction to hear of seamen working on board a ship in which they have, all of them, a decent life, free from unnecessary crude hardships. That such a state has been at last attained seems to justify the complaints of the neglect of hygiene and welfare at sea, voiced by THE LANCET and its contributors.[1] It remains to record our sense of the courtesy of the R.M.S.P. Company in permitting our representative to inspect their ship, and to thank the medical officer, Dr. J. W. Renton, for the assistance which he gave.

---

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

J. C. Soutter to be Surg.-Lt.

### SMALL-POX PRECAUTIONS.

A Fleet order calling attention to the increasing prevalence of small-pox in the North of England advises all officers and men serving in ships and establishments at home who have not been revaccinated within the last five years to be revaccinated. The warning has been posted on the notice boards of messes of ships and establishments.

## ROYAL ARMY MEDICAL CORPS.

Appointments made at the War Office: Maj. J. W. L. Scott to be Asst. Dir.-Gen., vice Maj. D. P. Watson (vacated).

Lt.-Col. A. O. B. Wroughton to be Col.

Maj. D. P. Watson to be Lt.-Col., vice Lt.-Col. A. O. B. Wroughton (promoted).

Maj. and Bt. Lt.-Col. O. Ievers to be Lt.-Col., vice Lt.-Col. and Bt. Col. Sir E. S. Worthington, to ret. pay.

Maj. A. C. H. Gray to be Lt.-Col., vice Lt.-Col. J. J. W. Prescott (promoted).

### SUPPLEMENTARY RESERVE OF OFFICERS.

A. Hemingway to be Lt.

### TERRITORIAL ARMY.

Capt. H. E. McCready to be Maj.

## INDIAN MEDICAL SERVICES.

Col. A. N. Fleming to be Hon. Surg. to the King, vice Col. P. Dee (retd.).

Capt. H. H. Brown to be Maj.

The King has approved the retirement of Lt.-Cols. R. F. Standage and W. Gillitt.

Lieut.-Col. E. W. C. Bradfield, late First Surgeon, Madras, succeeds Lieut.-Col. R. G. G. Croly as Civil Surgeon, Trichinopoly. Col. H. Ainsworth has been nominated a member of the Bihar and Orissa Legislative Council. Lieut.-Col. J. B. D. Hunter, agency's surgeon, Nepal, has been posted as Residency's Surgeon, Rajkot. Mr. R. Burn, member, Board of Revenue, United Provinces, has been appointed President of Board of Public Health, United Provinces, vice Mr. A. W. Pim.

Lieut.-Col. Croly, Dr. Diwan Ali, civil surgeon, and Maj. N. C. Kapur have been granted leave.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXIII.—STRICTURES OF THE URETHRA.

GONORRHŒA and trauma are responsible for the majority of organic strictures of the urethra. Lesions following the former condition are always situated in the penile urethra and never in the prostatic channel. They may be either single or multiple. When only one stricture is present it is most commonly placed in the region of the bulb, just in front of the triangular ligament. When multiple strictures exist, those situated near the external meatus are usually of larger calibre than those placed farther back and, moreover, are less amenable to treatment, a point of practical importance. Lesions resulting from trauma are usually associated with damage of the triangular ligament, in the neighbourhood of which structure they are invariably found. Fortunately, this type of stricture is uncommon, for it is extremely resistant to any form of treatment. Ulcerations following the impaction of calculi lead to a similar lesion. Spasm of the compressor urethræ, although not causing a stricture in the true sense, is often associated with an organic stricture and may act as a tiresome complication during the passage of instruments.

As a preliminary to treatment the following physical examination is required: (1) An external examination of the urethra, (*a*) to discover the site of the stricture and to obtain, if possible, some indication of its length and consistency, and (*b*) to define the presence of a periurethral inflammation, abscess formation, urinary extravasation of fistula; (2) a urethroscopic examination to define the site of the stricture, the position of its lumen in relation to the urethral wall, the presence of multiple strictures, and the existence of false passages; some of these points can also be demonstrated by the passage of varying sized bougies; (3) an examination of the scrotum, to exclude the existence of an epididymitis; (4) an examination of the abdomen for the presence of distension of the bladder or enlargements of the kidneys; (5) an examination of the urine as indicating the presence of urethritis or general infection of the urinary passages; and (6) a general examination of the patient as indicative of severe lesions—e.g., cystitis, pyelitis, &c.—resulting from such infections. The necessity for carrying out such an investigation is urgent, since simple uncomplicated strictures, as a rule, call for instrumental treatment, whereas complicated ones demand more radical operative measures.

### *Instrumental Treatment.*

The instruments used for the dilatation of strictures are either silk-web French bougies or graduated steel sounds. Filiform bougies are extremely useful in tight strictures, especially those accompanied by retention of urine. Silk-web bougies should be smooth and pliable, especially at the tip, and should range in size from Fr. 0 to Fr. 24. A set of steel sounds ranging from 0/0 to 14/16 is required. Great care must be taken in sterilising the instruments. Silk-web bougies may be kept in tubes through which formalin vapour diffuses, can be placed in weak antiseptic solutions or be boiled for a short period of time just prior to their passage. Steel instruments should, of course, be boiled. Care must be taken to keep the urethra as clean as possible during the use of dilatation methods, especially if there is any urethritis or infection of the urinary passages; free diuresis and antiseptic drugs should be given a day before and after the passage of an instrument; in addition the lumen of the urethra should always be washed out with weak solutions of antiseptics, such as potassium permanganate (1–8000), oxycyanide of mercury (1–6000), &c., both before and after the operation. Pain during the passage of instruments can sometimes be avoided by the instillation of novocaine (2–4 per cent.) into the urethra by means of a syringe; the use of warm lotions in irrigating the tract will sometimes prevent the production of spasm which may be induced by the passage of a bougie.

In passing filiform bougies extreme care must be exercised, as they are very prone to catch up the mucosa. If this persistently happens, the passage of a full-sized bougie down to the stricture will often stretch out these folds and permit of the successful passage of the finer sizes. The finer sized bougies are liable to catch in false passages; in this event leave the instrument in position and pass another of the same calibre alongside it; this may pass through the stricture. If the aperture in the stricture is eccentrically placed it is sometimes possible, especially if the urethra is filled with oil, to pass a fine bougie with its end tipped up in a manner similar to a "coudé" catheter. In the use of steel instruments the smaller sizes are to be avoided, for they are extremely liable to cause false passages; the larger sizes are especially useful in dilating cartilaginous strictures which run a tortuous course and are to be preferred to the silk-web bougies when the stricture has been well dilated. For example, silk-web bougies may be used up to Fr. 18 and then followed by the steel instruments. Sterile olive oil or liquid paraffin are the best lubricants.

The majority of strictures are cured by instrumental dilatation; three methods are in use—the slow or intermittent, the rapid or continuous, and the "forcible."

The *intermittent* method, consisting as it does in the passage of instruments at intervals of three to four days with the smaller sizes and weekly with the larger, is the preferable procedure as it is more likely to bring about satisfactory and permanent results; it has, however, the obvious disadvantage of prolonging the course of treatment, especially in obviously contracted strictures; moreover, it is not usually successful in its results in those strictures which have become markedly indurated and are only dilatable with difficulty. It is unwise to force the pace in the use of this method by too rapidly increasing the size of the instruments passed; it is better to stick to the rule of using the size smaller, the same size, and one size larger than that previously passed.

The *continuous* method necessitates the retention of bougies of increasing size in the urethra throughout the 24 hours, the urine being passed along the side of the bougie. This has the inevitable disadvantage of confining the patient to bed; at the same time it is a useful procedure to adopt in strictures of small size and especially in those where, for the convenience of the patient, a rapid dilatation is required. It is also valuable in some cases of urinary retention, for if a small-sized instrument is left in position even for a few hours, on withdrawal it will frequently be found that the patient can pass his water. In the treatment of tight strictures the method may be given a trial until the stricture is dilated to a reasonable size, when it may be replaced by the intermittent method. Some very indurated strictures which are unaffected by the intermittent method may respond to this procedure.

The so-called "*forcible*" *method.* Strictures should never be *forced*, but some strictures can be rapidly dilated at one sitting by the use of a succession of bougies or of such an instrument as a "whip" bougie. The method is applicable in those cases in which dilatation is urgently required; but it must only be used on a stricture of the annular type, composed of soft fibrous tissue which readily dilates. If this treatment is used in tough strictures the end-result may be disastrous.

### *Operative Treatment.*

In practice operative measures are seldom required; they are indicated, however, for the following conditions: (1) impassable strictures; (2) those which are indurated and cartilaginous and on which dilatation methods make no impression; (3) recurrent strictures; (4) those in which the passage of an instrument is painful beyond the endurance of the patient; (5) those in which the passage of instruments causes hæmorrhage or fever; (6) those in which a speedy cure is essential; (7) strictures associated with pathological complications, such as periurethral abscess, fistula, severe cystitis or pyelitis.

The methods in use are excision, internal urethrotomy and external urethrotomy. Excision of a stricture is practised in some cases, especially those which are single, are placed in the bulbous urethra, and are of the tough, cartilaginous type; the spongy tissue involved is excised together with the fibrous stricture. More commonly internal and external urethrotomy are indicated. The results of each are equally good, but the former is followed by a shorter convalescence. It can only be used where the stricture has a sufficient lumen to admit of the passage of the small bougie which is attached as a guide to the end of the urethrotome.

External urethrotomy by Wheelhouse's method is the operation of choice in all cases of stricture in the region of the bulbous urethra which are impassable and are accompanied by periurethritis, periurethral abscess, fistula, extravasation of urine or severe cystitis. It is not applicable except in cases of dire necessity for strictures placed far forward in the urethra since a permanent fistula may result.

### *Retention of Urine.*

Retention of urine associated with stricture is usually of the acute type, but may be of the chronic type accompanied by distension overflow. It is rare for a stricture to be so tight that no urine will pass through, although excessive indulgence in alcohol or over-eating will sometimes cause retention in the presence of a tight stricture, which might otherwise not occur; other causes of congestion of the urethra have similar effects. In these cases hot baths and the use of antispasmodic drugs will often give temporary relief.

The withdrawal of urine in cases of retention must be carefully performed as the sudden evacuation of fluid from the bladder may lead to suppression of urine, especially in cases of chronic retention. If it is possible to relieve the retention by catheterisation, the urine should be withdrawn slowly, complete emptying of the bladder being avoided. Sometimes the passage of a filiform bougie alone will enable the patient to pass his water naturally, either along its side or after its withdrawal; this should be followed by the passage of larger bougies; if this fails, then the smaller size should be left in position and the continuous method of dilatation proceeded with. If it is not possible to pass a catheter, an external urethrotomy should be performed, but circumstances may be such that this is not possible; a suprapubic puncture and withdrawal of urine through a suitably curved trocar and cannula may be carried out under local anæsthesia as an emergency measure. A preliminary incision of the superficial tissues is required; the same precaution of slow withdrawal of urine should be observed. This procedure should not be repeated if it is at all possible to divide the stricture.

### *After-treatment.*

Both after dilatation by instruments and by incision strictures show a strong tendency to recontract. Prolonged observation is required; it is not sufficient to restore the lumen of the urethra to its normal calibre; it must be kept fully dilated. As a prophylactic measure the full-sized instrument must be passed at regular intervals—first weekly, then monthly, two monthly, &c., until a period of six months has elapsed between two successive passages. If there is no evidence of recontraction the patient may be regarded as cured, but if there is any sign of recurrence, then the treatment must be prolonged; in any case the patient will be taking a wise precaution if he has the instrument passed at least once or twice a year during the next five years. The whole course of treatment, varying, naturally, with the type of the original stricture, may thus extend over a period of eighteen months to two years. In addition, it must not be forgotten that the infection of the urinary tract behind the stricture must be dealt with coincidentally.

## MEDICAL PRACTICE BY THE UNQUALIFIED:

### LORD DAWSON'S ADDRESS AT THE HOUSE OF COMMONS.

ON Feb. 24th Lord Dawson of Penn addressed a meeting of about 60 Members of both Houses of Parliament on the Medical Profession, the General Medical Council, and the Public. The meeting was held in one of the committee rooms of the House of Commons

Lieut.-Col. Fremantle, who presided, said that in October last a similar meeting had been held to investigate the claims put forward by osteopaths, chiropractors, and others for special registration. It was only fair that the doctors should now be allowed to have an innings, and Lord Dawson had kindly consented to come forward and state their case. Doctors sometimes differed from each other acutely, and those of them who were present would maintain their right to disagree with everything that Lord Dawson said. He asked members, therefore, not to take what Lord Dawson might say as necessarily expressing the opinion of the medical profession. On the other hand, however great might be their differences, there was one thing that member of the profession were unanimous upon—namely, to preserve the tradition entrusted to them to protect the interests of the public. The difficulty at the present time was that the public had not sufficiently recognised that the essential duty imposed on the General Medical Council by the Act of 1858 was the preservation of these interests. It would be of assistance to bear this essential principle in mind during the discussion.

### SUMMARY OF THE ADDRESS.

#### *Criticism of the Profession.*

Lord Dawson said that the subject of his address was not only somewhat complex, but had become overlaid in the last few months by much diffuse argument and some bitterness of spirit. Whatever his own shortcomings, he could at least claim experience. By set purpose he had kept in contact with every class of the community, rich and poor, and had rendered continuous service on the staff of a great hospital Yet never had he known the public criticism of the medical profession stronger than it was at this time. If he were told: "We chasten you because we love you," he would be tempted to retort: "Perhaps it was right to dissemble your love, but why did you kick me downstairs?" Of criticism in itself the profession made no complaint whatever; fair criticism was good for everybody, and perhaps it was more useful than praise. But in recent discussions there had been not a few suggestions that doctors were actuated by selfish class motives. That was not true. Doctors had the ordinary mixed motives of mankind. (If they were too good they would not understand their patients.) But was it likely that the doctor's life—with its long hours, its sacrifice of ease and leisure, and its contact with other people's troubles—would engender a selfish policy? The selfish, sordid view would be a negation of the doctor's work. True, the medical man had his foibles. He did not like a man who had made a discovery to make a secret of it; and if such secrecy was associated with gain the profession claimed the right to cast him out. That showed that in their ideals they put achievement before money. Again, if men were successful in their profession, their colleagues liked them to give up a certain amount of their time to unremunerative work in the service of others. And doctors were quixotic enough to inculcate principles of health which, if they were carried out, would go far to deprive them of their livelihood.

There was no doubt that at the present time there was disquiet in the minds of Parliament, the people, and the press, and it was right that the profession should meet the criticism and try to resolve the doubts. Controversy had turned on three topics; the grievances of Sir Herbert Barker and Dr. Axham, the work and status of the General Medical Council, and the relations of the profession to unqualified practice. Time would not allow him to deal with all of these subjects, and he would devote most of his address to the last because it largely covered the other two. In considering what should be the attitude of the profession towards unqualified practice, he wished to lay down two guiding principles. The first was that the good of the public should ever be the over-riding consideration. This the profession accepted without any hesitation whatever. The second was that the profession should avail itself of useful knowledge from whatever quarter it came. He ought to say at once that he did not contemplate that unqualified practice should be forbidden by legal enactment; the question at issue was rather whether unqualified practice should be recognised by the medical profession and the State.

#### *Diagnosis and the Medical Curriculum.*

A necessary preliminary to treatment was a knowledge of disease—its causes and its diagnosis. To attempt to treat disease without knowing what is wrong with the body as a whole (not with a part only) was admittedly an act of folly, and to gain such knowledge there must be careful organised training. Many people had an idea that when medical students were educated they were taught medicine from the outset. The average duration of the student's career as such was five and a half years, and it was sufficiently difficult to get the training into that time. The prime object was to educate the mind—certainly not to push in empirical facts. And half the student period was taken up with sciences which had no direct connexion with medicine: chemistry, physics, biology, physiology, anatomy, pathology. This education had to be carried on in buildings approved by an impartial authority. It was not concerned with medical theories, but with pure knowledge. There could not be two anatomies and two physiologies. It was not until the student came to his last two and a half or three years that he was taught disease; then he had to go into the wards, the post-mortem room, and the laboratory. And it was only at the end of his career that treatment came in, for it was recognised that the student could be quickly taught the principles of treatment if he was properly grounded. It was over treatment, however, that nearly all the controversies raged.

There should be no recognition of a man as an *independent* practitioner, said Lord Dawson, until he had had those years of training, and had studied the nature of disease and its diagnosis. And the training should be the same for all. In this matter there could not be the least compromise. Once a man had passed the tests at the end of his training no limits were placed upon him—he could follow his predilections. He might then, if he wished, become homœopath, osteopath, chiropractor, or anything else. If the osteopaths, for example, wished to further their cause, let them select able students, put them through the medical curriculum, and send them out as apostles of osteopathy. Truth would win. Some in the profession did, in fact, practise osteopathy, and their opinions were given a fair hearing. Having acquired the knowledge, a man was free to build what theories he liked, but not until he had learned his job. This principle held good in the faculties of law or engineering, and why should it not apply to medicine? Whatever a man's views on navigation might be, whatever his genius, he was not allowed to assume control of a ship until he had passed the tests prescribed for navigators. Why should less protection be [illegible] to the human ship sailing on the sea of life? [illegible] matter of training the profession would no[illegible] way.

### *Callings Ancillary to Medicine.*

Once a diagnosis had been made, continued Lord Dawson, there was room for greater latitude. It was possible that in the future treatment might be considerably delegated to callings ancillary to medicine which could usefully operate on their own lines under general medical guidance. A large share of maternity work was already done by registered midwives. The profession exercised a certain amount of control over them, but they still had considerable freedom of action. He would not refer to nurses; they stood alone and needed no argument; but he would be very sorry to try to do his work without them, for there were so many things that they could do better than he could. Still the profession maintained over them a coördinating control. There were already many other workers in the medical field—masseurs, operators of X rays and light treatment, bacteriologists—and if he found an osteopath with manipulative skill he would welcome his aid provided that proper diagnosis preceded treatment. There was no quarter from which the profession would not accept assistance in its proper sphere so long as it was conscientiously given. But to do good all methods of treatment must be coördinated under general medical guidance.

### *Evanescent Doctrines and Therapeutics.*

The profession must have an open mind, but it was part of its duty to protect the public from exploitation by stunts and fancies, even those which were honestly put forward. These stunts were always rising and setting, and in spite of constant failure, people recommended them in the most light-hearted manner without any apparent sense of responsibility. Each time it was announced that "further delay is criminal"; that "the medical profession is prejudiced against anything new"; that it has instituted "a sullen boycott": then follows a list of cases given up by doctors and cured by the new treatment. Deep in the human mind was implanted a belief in the miraculous, and everybody seemed to be striving for some short cut which would avoid the strait and narrow path of scientific endeavour.

Osteopathy had been so much in the public mind that it was desirable to say a word about it. In its practice it was manipulative, and was thus related to its forbear, bone-setting. Though the word bone-setting had been replaced by the term manipulative surgery, they meant the same thing, but not the same thing as osteopathy. The success of manipulative surgery depended on the use of gifted fingers, and in suitable cases such treatment was valuable. But accurate diagnosis was an essential preliminary. The doctor was not allowed to talk of his successes, but the manipulative surgeon had no such restraints. Was it to be supposed he talked of his failures? He would not be human if he did, but doctors knew that they were many. Human beings were not built in watertight compartments, and the most beautiful manipulation might be worse than useless if disease of the heart or lungs, a cerebral tumour, or gonorrhœa were the underlying cause of joint affections or of paralysis. Everyone was now trying to get control of disease more early, in its more curable stages, and hence diagnosis was of supreme importance. Undoubtedly the leading men in osteopathy were good manipulators, though the rank and file were bad. But good as their work might be they had no claim to be regarded as leaders and pioneers, and it was laughable to hear them proclaimed as such by the press. This country was the proud possessor of the greatest manipulative surgeon in the world, a man who had founded schools of manipulative surgery far and wide. Yet Sir Robert Jones's name was hardly ever mentioned, though he had more skill in his little finger than the osteopaths had in their bodies. The theory underlying osteopathy was that all diseases are due to displacements of vertebræ, and that all the remedies needed are manufactured in the body. Of course, it was sheer buffoonery; if it were true, it could be proved by X rays and by anatomical dissection. Osteopathy, moreover, already had its rival, chiropractic; whilst the very latest news was that a new heretical sect had been born under the name of napropathy. In a few weeks or months there would doubtless be a fresh addition to the succession of doctrines. How many was it proposed to recognise, and which?

### *The General Medical Council.*

In conclusion, Lord Dawson turned to the General Medical Council. It was in the public interest that the profession of medicine, like that of law, should have control and discipline. The personnel of the Council would vary from time to time, and hence its interpretation of its duties would also vary. Disagreement with its decisions might beget criticism of the members, but it did not justify criticism of the Council as such. He could recall occasions when the House of Commons had represented a very reactionary policy. This policy had justified criticism of that House, but it had not led to criticism of the House of Commons as an institution. He himself disagreed with the General Medical Council in certain particulars, but that did not absolve him from his duty to obey its edicts; if he objected to these his proper course was to try to alter them. If people disobeyed everything they disagreed with, where would be the discipline in life? There were occasions when, for conscience sake, a man should defy authority. But anyone who did this should be very careful that his defiance was not associated with material gain to himself. Could that be said of all the recent offenders who were dealt with by the General Medical Council? Lord Dawson thought not. It had been said that laymen should be nominated to sit on the Council. To that he had no objection, provided that medicine was not the only profession singled out for this dilution. A doctor, he thought, would do excellent work on the Bar Council, and the Trades Union Council might usefully admit an outsider—nominated, he would suggest, by the Home Secretary.

In thanking the meeting for its patient hearing, Lord Dawson declared that good work in medicine was never easy, never theatrical, never plausible, and asked his audience to distrust alleged wonder-working short cuts. "Narrow is the way" was as true of the search for knowledge as for salvation. The profession, he believed, was really actuated by singleness of purpose and was trying to keep aglow the lamps of science and service for the public good.

### DISCUSSION.

Colonel Aplin asked Lord Dawson to explain the relations between a doctor and a bone-setter called in to give his services after a diagnosis had been made.

Lord Dawson said that it would be impossible to treat on an intellectual equality any man who had not been through instruction in the basic sciences. In his limited sphere the bone-setter would be treated with the politeness due to a comrade, provided that he did not step outside what he did know.

Colonel Aplin asked whether Lord Dawson meant that no unqualified osteopath should be allowed to treat a patient unless the condition had first been diagnosed by a doctor.

Lord Dawson replied that it was not in contemplation to make the practice of the unqualified man illegal. The public could go to him whenever they liked; but the profession could only recognise him in the limited sphere already defined.

A Member asked whether the qualified doctor should be there at the time the treatment was given, to which Lord Dawson replied that there were individual differences. Some doctors took a more rigid view than others. If the osteopath was obviously honest according to his lights and was a colleague with whom the doctor could harmoniously work, he thought that he would be accepted as such. He could not say that all members of the profession would take up that attitude.

Mr. Neville asked whether the doctor would be charged with "covering" if he took the line just indicated.

Lord Dawson said that he was not prepared to lay down rulings, but in his opinion such a doctor would not be covering because he himself would be responsible for the treatment the patient was receiving. He would no more be covering than if he were employing a masseur or an unqualified expert in light therapy to carry out treatment which he himself had ordered and approved. Covering occurred when the initiative was taken by the unqualified man. It was dreadful that people should treat diseases of which they did not know the nature, and he would punish any doctor who countenanced that practice.

The Chairman asked Colonel N. King, Registrar of the General Medical Council, to speak on this matter of covering.

Colonel King said that Lord Dawson was correct in what he said. If a registered practitioner was responsible for the treatment, and took a patient to a masseur or a light specialist or anybody else, and said "I want a certain treatment given to this patient," covering would not arise, even if the doctor might not know exactly how to administer the treatment. But if the doctor were employed by the unqualified person, as Dr Axham was employed by Sir Herbert Barker, the position would be totally different.

Mr. Peto said that supposing Lord Dawson had sent a patient to be treated by Sir Herbert Barker and an anæsthetic had been needed for the treatment, would Dr. Axham have committed any crime against the laws of the Medical Council by administering it?

Colonel King replied that if the patient were Lord Dawson's patient, and his treatment was on Lord Dawson's instructions, then Dr. Axham would have been acting under Lord Dawson's direction, and the position would have been different.

Mr. Peto, referring to Lord Dawson's remark that doctors were ready to learn from other people, said that when Sir Herbert Barker offered to demonstrate his methods at any hospital selected by the medical profession, he had been met with a refusal. Why had he not been allowed to demonstrate his methods and to do his operations for the benefit of young students or anyone else?

Lord Dawson replied that he would deprecate the young student being dragged into any of these controversial questions. He would like to see a written document setting forth the terms of this offer of Sir Herbert Barker's; he had never been able to discover it, though it was constantly referred to in the press. Some of his (Lord Dawson's) colleagues had shown a friendly spirit and tried to see the work of osteopaths, but so often there had been an evasion or an excuse. If such an offer were made it would be easy to arrange a demonstration. And there was another way open to Sir Herbert Barker. He was a man of skill and had been successful financially. His fees were often larger than those of the ordinary surgeon. Lord Dawson had always found it difficult to understand why Sir Herbert Barker had not followed the example of members of the profession by holding a clinic for the free treatment of poor people where those interested could come and see him at work.

Mr. Peto said that throughout the war Sir Herbert Barker's one wish was to treat soldiers, in suitable cases, gratuitously; but not until 1918 did the War Office give half-hearted permission for men to go to Barker or any other bone-setter at their own risk. He had received a letter from Sir Herbert Barker in which he said that if the profession had only pocketed their pride and professional dignity years ago and learned what he could teach, all would have been well, and much unhappy criticism would have been spared; and, more important than all, humanity would have been an enormous gainer. He would send to Lord Dawson a copy of Sir Herbert Barker's offer to demonstrate his methods.

Lord Dawson said that he was not concerned with the wisdom of the action of the War Office. If the principles he had laid down had been applied in that case—if, before Barker treated them, the patients had been diagnosed by a skilled diagnostician—he would have raised no difficulty.

Sir Martin Conway put forward a problem. If he went to his family physician, who diagnosed what was the matter, and if he then said that he would like to go to an osteopath for treatment, and if in spite of the doctor's opposition he went, and the osteopath's treatment required a general anæsthetic, would a qualified physician be covering if he gave the anæsthetic?

Lord Dawson replied that that was a technical point. The real answer was that the range of treatment had now widened enormously, and included every kind of manipulative and physical measure, and hence it was likely that the definition of covering might have to be modified. It was not a rigid regulation; its great purpose was to protect the public, and for their protection treatment could not be allowed unless it was preceded by skilled diagnosis.

Mr Sydney Henn asked whether Lord Dawson would extend his strictures on methods of treatment devised by unqualified men to Mr Spahlinger's treatment for tuberculosis.

Lord Dawson replied that it was difficult to be fair and just about the Spahlinger treatment, because the profession in a general way was not acquainted with the facts. They would be very glad to know them.

Lord Knutsford wished to remind Members of the House of Commons who favoured unqualified practice that they had forbidden it in regard to dentistry. The House had laid it down (and the Lords had acquiesced in the decision) that no unqualified man should operate on the mouth at all. He did not know why dentists were treated more hardly than members of the medical profession.

Lord Balfour of Burleigh said that one reason for uneasiness in the public mind was that there was no appeal from the decisions of the General Medical Council. Perhaps it might be advisable to provide for such an appeal

Lord Dawson replied that on the question of an appeal he had an open mind. He was convinced that in the Council there was every intention to be fair and just. A legal assessor was present during the sittings, and he, the speaker, was satisfied that every man obtained justice.

The Chairman said that the opinion of the law officers, as prepared by Lord Justice Lopes and Lord Esher, was that it was only right that the profession should be judged by the profession. If an appeal were made to the Courts, it would be putting one profession under the judgment of another.

Sir Ellis Hume Williams pointed out that there was an appeal from one profession to another in the case of military law—namely, to the Judge-Advocate, who was a barrister. He asked what sort of practice napropathy was.

Lord Dawson replied that he had not been initiated into the mysteries of the cult, which attributed human ills to connective tissue. There was a constant succession of these cults. Unqualified practitioners who were left to themselves often suffered from ideas of grandeur, and made assertions of power which were very dangerous. That sort of thing could not be done in the profession; doctors had to place their proposals before their colleagues in scientific meetings, and in that way their vanity was kept down. He had watched a highly skilled masseur for years, and had seen him assume almost miraculous powers. He had, therefore, questioned him as follows: If there is an acute pain in the abdomen you can cure it in no time? Oh, yes! If the patient has had it only a few hours? Yes, certainly. If the patient has a temperature of 101°, would that make any difference? No. Or if he is vomiting? Oh, no—and so, step by step, he had led the masseur to declare that he could cure acute appendicitis by manipulations. That was the danger with people who had not had a rigid training.

Mr. Peto moved a cordial vote of thanks to Lord Dawson for his address.

# FROM CAGLIOSTRO TO COUÉ:

## IMAGINATION AS A METHOD OF TREATMENT.

*Report of an Address by*

DR. GUSTAVE MONOD.

*Delivered at a Social Evening at the Royal Society of Medicine on March 1st.*

Sir StClair Thomson, the President, received Fellows of the Royal Society of Medicine and their guests at a social evening in the Society's house, when Dr. Gustave Monod, of Vichy and Paris, gave an address on the above subject. After a few preliminary remarks upon the mechanism of suggestion, Dr. Monod illustrated his thesis from the lives of three men—of different centuries, professions, motives, and technique—who alike had reputation and success as healers: Cagliostro, charlatan of the eighteenth century; Gruby, physician of the nineteenth century; and Coué, pharmaceutical chemist of the twentieth century. He gave a vivid account of Cagliostro's life and wanderings, of his display of wealth, his claims to longevity, and of those qualities and those deceptions which led him to be called not a charlatan, but The Charlatan. With his programme for manufacturing gold and his healing panacea, he had become a speculator in human greed and the fear of death. Dr. Monod recalled Cagliostro's success in advertising his cures and the stories that were current about his miraculous powers. "Our consciousness of sanity and measure," he remarked, "is not easily overwhelmed, but is more vulnerable when we are possessed by emotions, by surprise, or even by the alertness of expectancy. This was the moment when Cagliostro loved to launch his attacks upon the astonished minds of his dupes." This "splendid rogue" might conceivably have deceived himself; but the fact for emphasis was that many of his cures were authentic. His cures were the basis of his success.

The story of Cagliostro was followed by an account of the technique of a practitioner whose name was unfamiliar to most of his audience.

### *Dr. David Gruby.*

David Gruby was born in Hungary in 1811. He studied medicine in Vienna and London, and arrived in Paris in 1840. A scientist and a hard worker, he specialised in morbid and comparative anatomy. At first he gave private lectures, but later he was invited to fill the chair of the great Cuvier. Settling on the height of Montmartre, where he established an observatory, he concentrated on the new science of microphotography, and collected 35,000 pathological specimens and secured 3000 photographic proofs. His other interests were many and various. He studied the hoof of the horse experimentally so as to obviate the use of horse-shoes; he opened a free dispensary; he managed an ambulance during the war—an ambulance without either deaths or amputation. He was a pioneer in the aseptic treatment of wounds, employing cotton-wool. He was naturalised as a Frenchman by national gratitude for his services. The City of Paris thanked him officially. Three medals were struck in his honour; 23 learned societies considered themselves honoured in having his name either on their honorary or active list.

So much for the savant. What about the man himself? He was certainly original. His consulting-room was littered with books which were only dusted when they fell on the ground. The prevailing colour in the room was green, but of every conceivable tone. Another room was used as a garden; he covered the floor with zinc and planted a number of plants which he watered ceaselessly. The room was a muddy mess where everything putrefied and the excess water percolated through to the indignant tenant below. Gruby was accustomed to throw everything into his bedroom and he needed a tunnel to reach his bed. When the exigencies of space demanded that the bedstead be removed, he slept in his consulting-room on his armchair, which he prolonged by heaps of books. Every night he plastered himself with a thick layer of calf's fat and then enveloped himself in paper, with the idea of nourishing his skin. His morning toilet lasted for hours, for he was strong on bodily cleanliness. Gruby had no regular consulting hours. The higher a client was in the social scale the longer he had to wait. He was supremely indifferent when clients complained, and would often leave them and go off on his round of visits in his celebrated roofless coupé, drawn by an ancient unshod horse, baptised *Va nu pieds.*

So much for the man. What was the technique of this savant, this pioneer in scientific biology, who was also a sound physician? The note was perfect simplicity, but he knew how to appeal to his patient's imagination. His amused, somewhat stunned patients obeyed him blindly; Gruby drove his simple, commonplace devices into their subconscious minds with unerring skill. His clientele comprised most of the celebrities of Paris. His prescriptions have become legendary. His Latin was all his own. His powders were chalk. His mixtures were water. But his remedies were only efficacious when they were taken with varied details. Always, without exception, they must be taken at precisely the hour prescribed. The precise diet was also advised.

A rheumatic patient was advised to take three apples; one at 7 at the Arc de Triomphe, another at 7.20 in the Place de la Concorde, the third in the Trocadero Gardens at 8. That meant a brisk morning walk, and the treatment, needless to say, was successful. A nervous member of the Stock Exchange, with persistent migraine, was ordered to go to Versailles by the 12.30, to eat an orange, and to return by the 2.24 train. He was, in this way, induced to give up his daily excitement at the Bourse. A lady, who suffered from intractable insomnia—one of those who "do not sleep a wink"—was ordered to take a spoonful of his famous water every half hour during the night. The nurse had no difficulty with the first two or three doses. But when the fourth was presented, the indignant lady insisted on being allowed to sleep in peace. He was called to a paralysed patient. He found her immobilised in her armchair. "What oil do you use in the kitchen?" "Why, ordinary oil, I suppose." "Can I see it?" When the bottle was produced Gruby uncorked it and calmly began emptying it on the carpet. The patient jumped up: "Hang it all, that's a Persian rug." The rug was ruined—the lady cured. Gruby's therapy was based on the device of using the patient's imagination to reinforce his own pre-eminent common sense. His astonishing successes earned for him the odd title of the "derviche guérisseur." The two Alexander Dumas, Chopin, Ambroise Thomas, Liszt, and Georges Sand were among his clients.

### *The Technique of M. Coué.*

The last half of Dr. Monod's paper was devoted to a dissertation on M. Coué, whom he described as Bernheim's disciple. Coué's craft, said Dr. Monod, consists in preparing a road, in making the path straight for the propulsion of concepts sufficiently potent to seize on the entire field of the subconscious mind. These ideas do not mature as a fruit of the will. They are unmistakably labelled with automatism. A simple phrase is repeated so rapidly that there is no time for reason to insinuate itself into the subconscient mind. *Ca passe*—repeated with the rhythm of a bee's wings. . . .

The logical cohesion of Coué's technique is striking. It is the unswerving applications of his principles in all their implications. But it is possible that he does not realise that in an atmosphere where bluff and stage management hold the world in their formidable grasp, his cheery good nature provides his patients with an astonishing and striking contrast. The more he repeats that he personally is of no importance the more he subjugates his hearers. The results that he obtains are, of course, the fruit of long experience. His public is won over as soon as he appears. He uses a conversational tone and a simple vocabulary. He begins the reassurance of his audience by reading his correspondence, including expressions of gratitude for cures and strange requests. A woman writes that as she was one of his convinced disciples she had bought two Panama bonds, but in spite of all, the numbers had not won. Criticism is at once disarmed and everyone laughs. Then he states his principles in a few words and proceeds at once to apply them. He tests the suggestibility of his patients in asking them to squeeze their hands tightly and to say to themselves that they cannot possibly loosen them. This experiment is sure to succeed. The forcible contraction of the hands is obviously voluntary. "Imagine that you can't do it." This is the addition of imagination to will; they are not in opposition. And the expert Coué, like a pointsman on the railway, has switched on the train to another line without the passenger being aware of it. Henceforth he can lead them where he wishes. His will has been substituted for the patient's will. The sitting concludes with a short peroration, always the same, which M. Coué recites in a monotonous voice, after having requested his hearers to close their eyes. Many of them instinctively join their hands in prayer. It is a short homily of optimistic philosophy with a little digression sketching out a few hints on digestion on the standard of a kindergarten class. One is amazed to hear M. Coué finish up by counting one, two, three so prosaically. Everyone looks as if they were waiting for an Amen, because it must not be forgotten that his stage management is borrowed from ordinary cultural rites.

All this is very dull, is it not? Perhaps! But I must now show you that it is a most formidable and disconcerting discovery. This is not prayer; M. Coué goes directly for his purpose. No, this is not prayer; it is an answer to prayer. You can call it M. Coué's answer to the Lord's Prayer. You will have your daily bread and you will digest it perfectly. "Even if you have imperious reasons, real obstacles which give you pain and grief, you will be free." In other words, your trespasses are forgiven. "If you are assailed by evil thoughts, temptations, I wish them all to be swept from your imagination." This is equivalent to saying you will not be led into temptation and you will be delivered from evil. "O, M. Coué," wrote a worldly woman, "I would like to pray to you. You are God Himself." I am not surprised.

It is obvious that M. Coué addresses himself to a definite category of morbid conditions. Mythomaniacs are an immense class. We are all of us more or less the subjects of mythomania, even the healthy people at the foot of the scale. At the other extremity, when mythomania is carried to excess, it becomes a psychosis, a disease of the soul. Between these extremes are found, in a zone with indefinite frontiers, a vast number of unhappy beings, the vain, who are possessed by a passion for attracting attention to their exceptional situation. They are always playing a part; they lie so as to provide themselves with stage scenery. They lie by word and gesture; they lie in thought and in body; they lie to the world, and they lie to themselves. The real drama is that they lie to themselves. They are caught in their own traps. They imagine a whole complex of contractions, deafness, blindness, and pains and aches without end.

Here is Coué's clientele. His immediate results, it is true, appear remarkable. The word cure runs trippingly on their tongues. And all is so simple. Coué is like a visitor to a golf club to whom the game is explained. Why, says he, do you pay out good money and give yourself so much trouble and walk so far carrying so many clubs? I'll show you what to do. Taking the ball between his thumb and index finger he calmly places it in the eighteenth hole.

### *Limitations and Perils of Auto-Suggestion.*

Dr. Monod continued to the following effect:—

A lesion is only curable by imagination if it has been produced by imagination. This law of reversibility is a general law in biology. Troubles complicating a lesion will disappear if they are imaginary and if the lesion be represented by 1 and the imaginary troubles by 99, then clearly the abolition of 99 per cent. of the total complex will be experienced as a miraculous result. But it is not a cure. Coué would say of a hernia: "The subconsciousness sees to it that the tear in the peritoneum heals up little by little." Actually the imagination can only suppress what it has added—pain, fatigue, anxiety—which is a great deal. The following is a quotation from Coué:—

> "The subconscient mind having accepted the idea that the fibroid must disappear, the brain orders the arteries which nourish it to contract. They do contract; they refuse their services, and as the fibroid is deprived of food it dies, dries, is reabsorbed, and disappears."

M. Coué admits that disease may be imaginary, but he has never told us that a cure may be imaginary. He says that his explanations are so simple that there are only two categories of people who do not understand him—imbeciles and those who refuse to understand. A third might be added—those who imagine that they understand. If you break a bone, says M. Coué, go to the hospital. Why does the brain not send the necessary orders to heal broken bones? Perhaps it is because X rays make such an irresistible appeal to reason. And no patient's imagination will refuse to yield to his indignation if there is a vicious union. M. Coué, it is clear, fights shy of controllable conditions, and here he shows the common sense with which he is so plentifully endowed. Unfortunately there are grounds for fearing that his disciples do not share his wisdom.

Everyone nowadays discusses medicine; it is so easy to be a healer. Overnight one may score over the ignorant oafs who have been at pains to work for a qualification. It is the strength of our would-be therapists that they know nothing. All doubts disappear from those who are amenable to Coué's influences, and all those small minds saturated with neighbourly love are mightily tempted; as also is the inevitable band of predatory exploiters which has always clustered round disease. M. Coué wishes us to concentrate on the good side of his method, but there are other aspects. He tells us that criminals are victims of auto-suggestion. Moreover, if the expectant heir repeats every morning: "I will sweeten Uncle Paul's coffee with arsenic," and Uncle Paul dies, there will be no peace. He will be torn by remorse. Can this also be charmed away? Perhaps not. M. Coué replies to one of his disciples: "You cannot possibly obtain relief in such a case as you describe, because, in this case the remorse really exists; it is a fact." Quite so. But is not a hernia also a fact?

### *The Lessons to be Learned.*

And now to conclude. One point is incontestable; without operators, healers, there is no cure. Cagliostro, Gruby, and Coué used the same mechanism in different ways; and they did cure their patients. The second point is that their cases all belonged to a definite category of patients. A third is that each of these wizards chose a foreign country for his field of battle. The Sicilian and Austrian chose France, the Frenchman England and America. (It is noteworthy that Coué failed absolutely in Italy.)

I maintain strongly that no physician can afford to neglect any kind of successful therapy. What Coué has taught us is that we should measure our patient's suggestibility. We must add a psychological diagnosis to our ordinary diagnosis; one patient demands authority, another persuasion, a third is worthy to be our collaborator, our partner in the search for truth; and all of them need and are grateful for our sympathy. But I claim that we can do this quite simply. The replies to our ordinary questions suffice. It is easy to see if your patients' answers are or are not suggested by your questions.

Above all, harmful suggestions must not be given. We have recently seen a play in Paris called *The Triumph of Medicine*. It was an acrid and penetrating criticism of our art. A Dr. Knock elaborated a new formula: "a fit man is merely a sick man who doesn't know he is ill." And so, full of his design to make money as soon as possible, he succeeded in persuading everyone in his village and in the neighbourhood that they were suffering from a highly variegated list of diseases. The walls of his consulting-room and his waiting-room were covered with coloured anatomical diagrams of pathological conditions. In a few weeks everyone succumbed and the inn was turned into a nursing-home.

Let us use good suggestions. Let the consulting-room suggest recovery rather than disease. What is the use of glass cupboards with shining instruments? They do not provide useful suggestions? Neither are unmeaning uncoordinated pieces of furniture suggesting a torture chamber to be recommended. Let us face facts as they are. Medicine was materialised when it made itself scientific. We have studied death rather than life. It is said that in America a physician has no need to see the patient; he has a number of reports from expensive specialists before him, and makes his decision from them. We must appeal to our patient's reason. Yet how often do we discuss the therapy of the mind with our students? Psychotherapy must be taught.

Why should we not profit by Coué's lessons? He gives us a lesson in medical history. Coué has pulled us up, and with a round turn we have gone back to pre-Hippocratic days. We have retrogressed into the period of magical incantations. *Everydayineveryway* is no more and no less than *Abracadabra* sung or hummed in modern English. And this is fashionable also, is it not? Tired out with the faultless order and serenity of the Ninth Symphony we fly to the primitive jazz of the negro as a salve for wearied minds.

Coué is absolute in his methods, and to my mind his greatest merit is supreme simplicity. In the troubled days we are to live in for the rest of our lives we must hold to our own ground and we must not imitate. These three healers are, above all, themselves—Cagliostro, the perfect rogue; Gruby, absolutely original; and Coué, who has succeeded because he pushes his principles to their logical limit. Coué does not even need to apply his principles; he lives them, and the rest follows as night follows the day.

Our therapy will, I venture to think, improve if we develop our personality. We do not need either to will or to imagine, we must be ourselves. Let us put our faith in our work. Let us put our hope into our therapy. Faith and hope, the foremost virtues. The third and greatest is charity.

## MEDICINE AND THE LAW.

### THE THREE YEAR SENTENCE.

IN presenting a recent criminal appeal (against the sentence of three years' imprisonment passed on Hayley Morriss) counsel contended that the decided cases showed that no one should be imprisoned in a local prison for more than two years; "the principle was that no man could endure being shut up with lack of exercise and fresh air for longer than two years." The accused had been sentenced to two years' imprisonment with hard labour on one charge and to an extra year without hard labour on another. In rejecting the appeal the Lord Chief Justice suggested that Parliament should remove what he called a blemish from our penal legislation and should provide for increased penalties—i.e., penal servitude—where a multiplicity of offences—not necessarily of a sexual nature—has been committed, and where punishment is at present limited to two years' imprisonment. Mr. Greaves-Lord's Criminal Justice (Increase of Penalties) Bill is the outcome of Lord Hewart's suggestion; it has quickly passed its second reading and has received Home Office approval. It briefly proposes that where a man is convicted of two or more offences punishable by imprisonment which might amount in the aggregate to three years or more, the court shall have power to sentence him to penal servitude.

English criminal law, if allowed time, adapts itself eventually to changes in public opinion, usually in the direction of lighter penalties. When the death sentence was no longer thought essential for a large number of offences, transportation found its way on to the statute book. When in turn the barbarity of transportation was recognised, penal servitude was evolved as a statutory substitute. Penal servitude was standardised as a punishment of the duration of three years or more. The Penal Servitude Act of 1891, which effected this standardisation, at the same time allowed a judge to award imprisonment (with or without hard labour) for a term not exceeding two years in cases which seemed not to merit penal servitude. Thus, by a kind of convention the internment of offenders became separated into two compartments—on the one hand imprisonment up to two years, on the other penal servitude for three years or more. Each had its own conditions of work, dietary, and confinement, and these were relatively so different that many convicted persons preferred—and would even implore judges to inflict—three years of the latter rather than two years of the former. Two years' hard labour was spoken of as almost a death sentence; five years' penal servitude was by comparison almost a healthful holiday. Doubtless, as Mr. Greaves-Lord said lately in Parliament, in the early days of imprisonment with hard labour, a man who was able to survive two years of it came out of prison completely broken. In upsetting a sentence of three years' imprisonment in the case of R. *v.* Goldstein in 1916, Lord Reading was unquestionably influenced by considerations of health. Now, however, it seems, conditions are entirely changed. The Home Secretary stated in the recent debate that, after watching men at work who were respectively serving terms of hard labour and of penal servitude, he is satisfied that there is no longer any difference between the two, and that the quantity and quality of the food is as good in the one case as in the other. If this is so, and if conditions are really the same in the two-year as in the three-year period, there seems no point in retaining the old distinction between imprisonment and penal servitude. The latter description has a harsh sound no longer appropriate. The old classification seems, in fact, to have become as obsolete and arbitrary as the distinction between felonies and misdemeanours, a mere matter of historical development to which the law still clings tenaciously.

### LOCAL AUTHORITY'S POWER TO PROHIBIT MILK-SUPPLY.

Common sense triumphed over technicalities in The King *v.* Hale U.D.C. (*ex parte* Wright) reported in the *Times* of Feb. 24th. The question, said the Lord Chief Justice, was whether it was safe that milk should be distributed for human consumption from a farm where there was a cow which was "a sort of reservoir of potential diphtheria." The facts of the case were instructive. In December, 1924, an alarming outbreak of diphtheria occurred in Cheshire. The cause of infection was traced to a dairy. The milk was then traced to a farm in the area of the local authority of Bucklow. The medical officers of the Hale and Bucklow districts made prompt investigation and found six out of seven persons at the farm suffering from diphtheria. The patients were sent to hospital and the Hale council served a statutory notice (under Section 4 of the Infectious Diseases (Prevention) Act of 1890) calling upon the farmer to show cause why an order should not be made prohibiting any further supply of milk from his farm. The farmer was at the moment in hospital and his father-in-law consented on his behalf to the order, this being apparently the technical irregularity on which the farmer afterwards relied in court. A cow at the farm was found to have diphtheritic germs in a sore udder. The sore afterwards healed; the cow had a calf, and the cow's milk was free from germs; but the local authority was not satisfied that it was safe to remove the embargo so long as the cow, a potential source of diphtheria, remained on the farm. In the course of time (a year later, it was stated) the farmer applied to the courts for a *certiorari* to quash the order or a *mandamus* to compel the local authority to withdraw it. He relied on the technical irregularity in omitting to comply strictly with the procedure under Section 4 of the 1890 Act, and he pointed out that the cow was now well. The local authority replied that it would remove the embargo if the cow were slaughtered, the loss involved by slaughter being apparently a matter of only £5. The farmer rejoined that the council had no right to impose a condition of slaughter; only the Minister of Agriculture could do so. Thus, for the sake of what counsel described as a certain "bovine obstinacy," law costs greatly in excess of the sum of £5 were incurred. The farmer lost his case and had to pay the costs. Lord Hewart said the irregularities on the part of the council were neither large nor comprehensive. It was not a case either for *certiorari* or for *mandamus* The court refused to take the responsibility of deciding that, with this cow still upon the farm, the local authority should be compelled to permit the distribution of milk therefrom.

### A QUESTION OF SURVIVORSHIP: MEDICAL EVIDENCE INCONCLUSIVE.

If two or more persons perish in a common calamity, and if the circumstances leave it uncertain which of them died first, the law will in future presume (for the purposes of title to property) that the deaths occurred in seniority, the younger surviving the older. This has been the position since the beginning of this year in consequence of the new Law of Property Act. Previously the law in England made no such presumption but examined the evidence and, in default of evidence, left the question of survivorship unanswered. What will perhaps be the last case under the old law has just been heard in the Probate Court. In a crash near Croydon in December, 1924, an aeroplane containing a pilot and seven passengers dived to earth nose foremost. The petrol tanks burst; a fierce fire broke out, and the whole party lost their lives. Among the passengers were a husband and wife. The husband, as it happened, was illegitimate, had made no will, and left no issue. If his wife could be proved to have survived him, she would take her share of his estate, and at her death her next-of-kin would benefit. If she did not survive him, the property went to the Crown. The wife's body was found underneath all the others. Her burns were chiefly post mortem and there was a head wound which had lacerated the left lobe of the brain. Dr. R. M. Brontë, who made a post-mortem examination, found extravasation of blood, indicating that the wound occurred before death. The husband's burns were mostly ante-mortem. He had a fractured pelvis and other injuries, but Dr. Brontë found no extravasation of blood in his case. The judge accepted this evidence but found it inconclusive. "I know," he said, "that these two persons were killed; that the skull of one was fractured in life; that the other had a fracture sustained after death; that both were burned while in life; and that both bodies were burned after death. At what period of time in the progress of the collapse of the machine they died, I do not know." Thus, in accordance with the law in force at the time, the judge left the question of survivorship unanswered for want of clearer evidence. The wife's next-of-kin failed to discharge the burden of proof which the law laid upon him, and the husband's estate was awarded to the Treasury. Lord Merrivale remarked that he had had every possible assistance from the medical men called on both sides, but he could not eliminate the doubt arising out of the series of possible causes of death—shock before burning, burning, shock upon impact with the ground, and injury by fracture occurring either before, or upon, or after impact with the ground.

THE Annual Oration of the Hunterian Society, entitled "The Private Practitioner as Pioneer in Preventive Medicine," has been printed as a booklet by the Oxford University Press, and is now on sale, price 1s. net.

# NATIONAL HEALTH INSURANCE.

## EXTENSIONS OF BENEFITS.—RECOMMENDATIONS OF THE ROYAL COMMISSION.

THE Report of the Royal Commission on National Health Insurance appears this week (H.M. Stationery Office, Cmd. 2596, 6s. 6*d*.). The Commission was appointed in July, 1921—

> "to inquire into the scheme of National Health Insurance established by the National Health Insurance Acts, 1911–22, and to report what, if any, alterations, extensions, or developments should be made in regard to the scope of that scheme and the administration, financial, and medical arrangements set up under it."

The membership of the Committee consisted of Lord Lawrence of Kingsgate (Chairman), Sir John Anderson, Sir Humphry Rolleston, P.R.C.P., Sir Alfred Watson, Sir Arthur Worley, Sir Andrew Duncan, Mr A. D. Besant, F.I.A., Mr. Fred Bramley (resigned March, 1925), Mr. James Cook, Mr. John Evans, Prof. Alexander Gray, Mr. William Jones, Mrs. F. N. Harrison Bell, Miss Gertrude Tuckwell, with Mr. E. Hackforth (secretary) and Mr. J. W. Peck (assistant secretary).

The Report itself is divided into a Majority Report (292 pages), a Minority Report (27 pages), and two appendices containing the reports of the Departmental Actuarial Committee and a list of persons and bodies by whom evidence was submitted. We comment in a leading article upon the general conclusions and recommendations of the Majority Committee; the latter summarises as follows the contemplated development of the health services and the directions in which extension is desirable.

### CONTEMPLATED DEVELOPMENT OF THE HEALTH SERVICES.

The various medical services organised by the State will continue to expand both in their scope and in the range of persons to whom they apply. These services should be maintained in close relationship with each other, both at the centre and in their local administration In considering any changes or developments in the Insurance Medical Service regard should always be had to the importance of the fullest possible coördination with other health services.

Medical benefit has been a valued and successful element in the scheme of National Health Insurance. While it has been inevitable hitherto that medical benefit should be confined to a general practitioners' service, this limitation has detracted from the value of the benefit and its removal is urgently desirable. The additional benefits of a treatment character have been, on the whole, successful and appreciated, though in varying degrees, but they suffer from the following defects inherent in the conditions under which they are provided.—

(*a*) They are only available for those insured persons who are members of societies having surpluses at valuation, and only for those members who fulfil certain qualifying conditions, and that consequently large classes of insured persons are debarred from participating in these valuable services.

(*b*) Even among the societies giving a particular type of treatment benefit there is no uniformity in the content of the benefit, with the result that there is widespread confusion in the minds of the insured persons as to what precisely their rights are.

(*c*) The arrangements made between societies and professional bodies are wanting in authority and uniformity, and in some cases are accompanied by undesirable conditions.

It is desirable that, as soon as funds are available, the scope of maternity benefit should be expanded to cover medical and midwifery services in addition to a cash payment; that the service element should then be administered by the local health authorities and be coördinated with the other local medical services; and that a cash element should be retained and be administered in connexion with the other cash benefits.

### Recommended Extensions of Benefits.

The extensions of statutory benefits, to be made as and when funds are available to meet the cost, should be placed in the following order of priority :—

(*a*) Extension of the scope of medical benefit.

(*b*) Provision of allowances in respect of dependants of insured persons in receipt of sickness or disablement benefit.

(*c*) Improved provision at the time of pregnancy and childbirth for insured women and the wives of insured men.

(*d*) Provision of dental treatment as a normal benefit.

### *Medical Benefit.*

The extension of the scope of medical benefit should take the form of the provision of

(*a*) expert medical advice and treatment for persons who can travel to meet the specialist ;

(*b*) expert advice for persons who are unable to travel ;

(*c*) laboratory services ;

but in-patient treatment in hospitals, major operations in the home, maternity services, and dental services should not be included at present.

The extended service should be provided not by way of development of the out-patient work of the hospitals, but through an independent scheme organised, under the general direction of the Ministry, throughout the whole country by the insurance committees or their successors, as an integral part of medical benefit.

Provision should be made in the scheme for the closest cooperation between the general practitioners and the specialists, particularly for the exchange of information as to cases and for the giving of definite guidance to the general practitioner as to both diagnosis and treatment.

Any practitioner possessing the requisite qualifications should be entitled to take part in the work, and the decision as to whether particular practitioners possess these qualifications should lie in the hands of a mixed lay and medical committee for each area.

In the initial stages of the scheme arrangements might be made for patients who are able to travel to attend either at the specialist's consulting-rooms or at the out-patient departments of hospitals, or at clinics established by the local administrative authority, as may be found most convenient in various areas.

The scheme of extended medical benefit could be financed through the funds made available under a scheme of pooling of surpluses.

Ophthalmic benefit should be recognised as part of the expert out-patient service under the scheme, and should not be available except on the recommendation of a medical practitioner.

### *Sickness Benefit.*

An increase in some form of the normal cash benefit payable during incapacity for work is very desirable. For financial reasons this increase must at present be limited to an allowance in respect of dependants, where sickness or disablement benefit is payable, on the following lines :

(*a*) An addition to the sickness benefit of 2*s.* a week in respect of each dependant.

(*b*) An addition to the disablement benefit of 1*s.* a week in respect of each dependant.

(*c*) The dependants' allowance should be paid in all cases of incapacity of an insured married man even where the wife is herself a wage earner.

(*d*) The dependants' allowance in respect of dependent children should only be paid from the husband's insurance, not from the wife's.

(*e*) The dependants for the purposes of the scheme should normally be the wife and the children up to 14 years of age, but in order to meet the case of the widower with dependent children, an additional 2*s.* in the case of sickness benefit and 1*s.* in the case of disablement benefit should be paid in such case.

(*f*) In the case of the insured widow with dependent children, the allowance should be paid only in respect of the children and no additions similar to those in (*e*) should be made thereto.

(*g*) In the case of the insured woman whose husband is uninsured, no allowances in respect of dependent children should be paid from the woman's insurance.

(*h*) In the case of unmarried insured women, no allowances should be paid in respect of dependent children, but additions at the rates of 2*s.* to sickness benefit and 1*s.* to disablement benefit should be paid in respect of a widowed mother living with the insured person and not having sons to whom she can look for support.

### *Other Benefits.*

No change should at present be made in the existing provision for maternity under the insurance scheme.

While a complete dental service available to the whole insured population would be an eminently desirable addition to the insurance scheme, no such change is financially practicable at present, and therefore the general arrangements for dental services under additional benefit schemes should be continued.

In order to secure more uniformity in, and effective supervision of, these services a regional dental staff should be instituted in a form that may be appropriately expanded when a statutory dental benefit is feasible ; and a substantial proportion of the cost of the regional dental staff should be borne by the approved societies providing dental benefit.

Owing to considerations arising from a survey of the development of the various medical services provided or supervised by the State, and having regard to the very large cost involved, no extension in the direction of provision of medical benefit for the dependants of insured persons should be made.

### Administration of Medical Benefit.

The Commission recommends that Insurance Committees be abolished and their powers and duties transferred to committees of the appropriate local authorities, such committees to contain possibly a proportion of coöpted members.

In regard to the remuneration and control of insurance practitioners, the Commission recommends that the capitation method of remuneration of the insurance practitioners be continued as the normal method, but that the attendance method be retained as an alternative for adoption in particular areas when so desired. It is desirable, they think, that any settlement of the rate of remuneration of the insurance practitioners should be made valid over a reasonable period of years, so as to avoid financial uncertainty to both the contracting parties. The existing machinery for regulating admission to and removal from the medical panel, and for dealing with complaints as to the conduct of practitioners, chemists, and patients is held to be necessary and to operate fairly. This machinery should be continued generally in its present form, except that where, on an inquiry resulting from representations that an insurance practitioner should be removed from the panel, it is decided that such removal is not justified, the practitioner should be given an opportunity of a further hearing before any lesser penalty is imposed by the Minister.

---

## PARIS.

(From our own Correspondent.)

### *Athletics and Cardiac Lesions.*

During recent years military inspection of young recruits has revealed the frequency of heart lesions traceable to over-indulgence in athletics and competitive contests, especially without adequate preparation. Such cases, according to recent reports, are diminishing in number, and it appears that in France sports and athletics are being practised on a saner physiological basis than formerly.

### *Protection of the New-born against Tuberculosis.*

Prof. Calmette has just reported to the Académie de Médecine on the results of his investigations in collaboration with other workers at the Pasteur Institute on the protection of the new-born against tuberculosis by means of the vaccine known as B.C.G. (Vaccin Bilié Calmette Guérin). His experimental research, it may be recalled, has established the following facts: (1) Immunity against infection or reinfection with tuberculosis can only be produced by preliminary inoculation of sensitive individuals with living bacilli. (2) To ensure that the organisms used for this inoculation are tolerated by the lymphatic tissues and do not form tuberculous lesions, they must be of a strain which in the course of generations has been deprived of the power of forming tubercles and which cannot recover that power even in favourable circumstances. It is necessary, of course, that the bacilli should keep their antigenic properties and should still be able to produce tuberculins. (3) It is only possible to forearm those subjects which have not been exposed to any previous infection. (4) Protection can be afforded either by inoculation of B.C.G. or by its administration by the mouth. (5) In this country, which has long been civilised, infection is so widespread that inoculation should be done during the first ten days of life.

Prof. Calmette's investigations have been made on more than 5000 children in France, 117 in Belgium, 3352 in Indo-China, and 218 in Senegal; so that they cover many different races. Whereas the mortality from tuberculosis amongst European children up to 1 year of age brought up in infected households is never less than 25 per cent. (in Paris it is 32 6 per cent.), the death-rate amongst those treated with B.C.G. vaccine is less than 2 per cent. The treatment thus saves at least 92 per cent. of the children who would otherwise die from tuberculosis in the first year of their lives. From the experimental data and observations collected during the past five years by Prof. Calmette it is now clear that this inoculation of the new-born is not only quite safe, but is also certainly effective. It therefore seems desirable to encourage its use by doctors and to recommend its employment above all in families in which the children are exposed to infection. The immunity conferred by the vaccine appears to last from 15–18 months, and it is desirable that re-vaccination should be done towards the end of the first and of the third years. It goes without saying that the treatment does not permit of any relaxation of the hygienic precautions intended to prevent massive infection of the young.

### *Testing Sanocrysin.*

Calmette, Bernard, Bezançon, and other French investigators are testing sanocrysin in tuberculosis. Results have varied and it is stated that indications cannot yet be given precisely, though the preparation seems most useful in recent and progressing caseation. Sanocrysin appears to modify the lesions; its specific effect is rather doubtful and its action variable, so that conclusions on its therapeutic value are not yet warranted.

### *Death following Antitetanic Injection.*

Deroide, of Calais, reports the rapid death of a 5-year-old girl following a single subcutaneous injection of antitetanic serum. The serum, injected prophylactically 24 hours after wounding of the foot by a nail, was prepared by the Pasteur Institute. The label stated that it would be effective until October, 1926. One or two minutes after receiving the serum the patient made convulsive movements, evinced distress at the throat, and rapidly collapsed. All emergency measures, including intracardiac injection of adrenalin, were vain. This case appears to be the first of its kind. The patient had never previously received parenterally any foreign protein. The case will draw renewed attention to the Besredka method of preventing anaphylactic shock by giving progressively increasing injections.

At the Paris Ophthalmological Society Valude and Autrevoix recently showed a case of ocular tuberculosis coming on in a child of 6 months, who died of meningitis three months later. The ocular lesion was supposed to be a tumour, until enucleation revealed extensive tuberculous infection. The lens and its ligaments were the only unaffected structures, and lesions were particularly marked in the uveal tract, retina, and optic nerve. The youngest case of ocular tuberculosis hitherto reported was aged 18 months.

Berthelot, Risler, and Foveau de Courmelles have just reported to the Académie des Sciences several cases of injury occasioned by ultra-violet rays. These injuries have occurred in persons making spectroscopic tests and in blowers of the glass bulbs used for incandescent lamps. Lamps having very thin walls may allow the ultra-violet rays to filter through. The lesions generally produced are painful erythemas and conjunctivitis.

Mouriquand has just transmitted to the Académie des Sciences, through Prof. Widal, a communication showing that a maize diet is not alone a sufficient cause for pellagra; it must coexist with poverty and under-nourishment. This opinion largely supports that advanced by Goldberger and his associates.

## HAMILTON DRUMMOND MEMORIAL FUND.

*To the Editor of* THE LANCET.

SIR,—In your issue for Oct. 24th last you published a first list of subscribers to the above fund. Since that date further sums have been received or promised from those whose names follow, making in all a total of £533 17*s.* 6*d.*

Dr C. N. Armstrong, Dr. Sarah B. Allen, Dr. Wm. Anderson, Dr. Paige Arnold.

Mr. I. Brumwell, Dr. H. S. Brown, Mr. W. Girling Ball, Dr. E. F. Bell, Mr. A. J. Blaxland, Dr. Leonard F. Browne, Dr. Percy Bennett, Dr. J. F. Bridge, Dr. Monica Bell, Dr. E. C. Braithwaite, Dr. Blench, Dr. Beaton, Mrs. G. F. Bengough.

Mr. H. W. Carson, Mr. Lionel Colledge, Miss Jessie D. Carr, Mr. Ralph Carr, Dr. J. F. Crombie, Mr. F. G. H. Clayton, Mrs. F. G. H. Clayton.

Dr. Alfred Duke, Mr. Sydney Dunstan, Dr. K. S. Dickinson, Dr. R. Leslie Dagger, Mr. Fred E. Dotchin.

Dr Robt. Forsyth, Dr. S. B. Fox, Dr. C. B. Fox, Dr. H. N. Fletcher, Prof John Fraser.

Dr. C. N. Gover, Dr. Helen Gurney, Dr. John Galloway, Mr. Gordon Gordon Taylor.

Prof. Howden, Prof. W. D. Halliburton, Dr. P. Henderson, Dr. J. Berry Haycraft, Dr. Jas. Hudson, Dr. W. A. Hewitson, Dr. Hobbs, Dr. Willmot Holmes, Mr. C. W. M. Hope, Dr. R. S. Hindmarch, Dr. Phyllis Herbertson.

Dr. J. Stanley Johnson, Dr. Maurice E. Jones.

Mr. and Mrs. Kirkbride.

Dr. Leathart, Dr. W. E. C. Lunn.

Mr. R. G. E. Mortimer, Mrs. Morel, Mr. J. McGregor, Sir Berkeley Moynihan, Mr. Geo. Mason, Dr. A. C. H. McCullagh, Dr. J. W. McNee, Dr. Wm. Mackenzie.

Sister Nichol.

Dr. Walkinshaw Oselton.

Dr. Ivan Pirrie, Mrs. Pirrie, Mr. W. Mark Pybus, Miss A. M. Parsons, Dr. G. Newton Pitt.

Mr. R. Russell, Dr. Amy Robinson, Royal Victoria Infirmary (Resident Medical Staff, Miss Brown (matron), Assistant Matron and Nurses, Lay Staff).

Mrs. R. E. E. Spencer, Dr. Wm. Seymour, Mrs. Shiel, Miss Shiel, Dr. Una Swanston, Dr. F. W. Sinclair, Mr. Fred E. Schofield, Mr. G. G. Shiel, Dr. T. E. Stoker, Mr. Fred Straker, Dr. J. A. Stobbs.

"Thankful Helper," Dr. W. A. Tweddle.

Sister Whitfield, Dr Olive Wilson, Prof. P. D. Wilkie, Dr. G. J. Williams, Sir Cuthbert Wallace.

In addition a sum of over £280 has been subscribed by past and present officers of the Northumberland Yeomanry. Doubtless there are still many others who will wish to join in this tribute, and the Committee will be glad if they will do so at once. Individual subscriptions for any amount not exceeding five guineas may be sent to the treasurers: Prof. R. P. Ranken Lyle, at 11, Osborne-terrace, or to Mr. Philip E. Noble, at Lloyds Bank, Grey-street, or direct to me at The Hawthorns, Osborne-road, all in Newcastle-upon-Tyne.

I am, Sir, yours faithfully,

G. GREY TURNER,
Convenor of Committee.

March 1st, 1926.

## FREEDOM RESEARCH FUND AT THE LONDON HOSPITAL.

*To the Editor of* THE LANCET.

SIR,—In August last a gentleman, who desired to remain anonymous, called here and stated that he wished to make a gift for some charitable purpose and asked advice. We had many conversations and eventually he agreed with our suggestion that most good could be done by endowing medical research, which was badly handicapped in this country because there was little or no inducement for a man to take up research as a life-work. We pointed out the uncertainty of the pecuniary prospects of those who took up research work at the beginning of their careers and he agreed with our views.

We drew up a trust deed embodying points which we considered essential—namely: first, that the sum he intended to give should be invested in trustee securities; and secondly, that the income should be spent in salaries and not on bricks and mortar, and not in laboratory equipment.

Later the donor presented £50,000 in such a way that no one could possibly trace its source, and it has been invested.

The Fund, which is known as the Freedom Research Fund, is managed by a small committee of three persons—a nominee of the donor, the head of the clinical laboratory, and the house governor of the hospital—who meet fortnightly.

The researchers appointed have the following advantages: (1) They will work in very fine laboratories entirely on research work, but shoulder to shoulder with the hospital laboratory staff, who are doing the routine investigation work of the hospital. (2) They will be in touch with the clinical work of the hospital and especially with the "medical unit." (3) They will be working in a centre where unlimited clinical "material" may be found.

We hope to enlarge the Fund.

I am, Sir, yours faithfully,

E. W. MORRIS,
House Governor.

London Hospital, E., March 1st, 1926.

## THE MEDICAL EXAMINATION OF PASSENGERS TO AMERICA.

*To the Editor of* THE LANCET.

SIR,—The right to subject passengers landing on American soil to any form of medical examination cannot be denied. The procedure in 1924 and 1925 was interesting and instructive to myself, when I was present. Off Ellis Island the passengers were assembled and passed before the medical officer and other officials who were assisted by the ship's surgeons furnished with a complete list of passengers. On lying up at the quay the passengers were again assembled in the drawing-room. An American medical officer in uniform stood at a table; on the opposite side a steward, with a list of passengers. One by one we were called up. Coming at the end of the list, I had an excellent opportunity of observing the method employed. The medical officer had a small stick which he laid upon each eyelid and turned up the lids. Then the hands were held out for inspection, the spaces between the fingers being carefully scrutinised. During the examination of about one hundred first-class passengers, I noticed the medical officer dip his fingers in water twice and the stick once and wipe them on a towel: this seemed to leave something to be desired. The examination was obviously for trachoma and scabies. Some months later there was in the press an account of an action brought against the Ellis Island authorities on behalf of a lady who claimed to have contracted trachoma in one eye as a result of the examination.

I enclose my card, but my name is not for publication.

I am, Sir, yours faithfully,

SURGEON.

Feb. 25th, 1926.

## TWO CASES OF EMPYEMA:

### A CONTRAST AND A RECORD.

*To the Editor of* THE LANCET.

SIR,—These notes upon two cases are not presented as detailed clinical records, but the outlines are sufficiently full to permit comprehension of the facts.

CASE 1.—A woman in domestic service came under my care with the history that she had been ill for about a month with a pain on the right side just under the lower ribs. About the end of the first week of symptoms she called in a doctor, who continued to attend her for three weeks, but not feeling better she came home and I saw her. On examination I found the usual signs of pleuritic effusion on the right side and used the aspirator. This proceeding I repeated four times at intervals of about a week, evacuating on each occasion from 1 to 1½ pints of pus. Seeing that the case was not following a satisfactory course I advised a resection of a rib. The operation was quite satisfactory as to emptying the pleural cavity, but the after-treatment was tedious and very prolonged, and she is most probably an invalid for life.

CASE 2.—A man aged 35, a loose-jointed, flabby subject, came under my care a short time after Case No. 1. I found him suffering from all the symptoms of pneumonia on the left side; by the end of the first week he developed pleurisy with later effusion. After resort to the usual remedies for about a week I used the aspirator. I withdrew one pint of inodorous pus, and three days later I again used the aspirator and evacuated eight pints of pus at one sitting without, apparently, the least inconvenience to the patient. His temperature at that time, 103·6° F., fell to 100° and never again rose above it. From this point he made a rapid recovery, the heart regained its normal position, the respirations became natural, and the chest resonant all over; in three months, or a little more, from the beginning of his illness he resumed his employment. He is now a gardener doing real spade-work without effort, and a year later I found him a strong robust man.

In contrasting these cases I cannot resist the conviction that had the aspirator been resorted to at an earlier stage in Case No. 1 the woman would have had a reasonable prospect of permanent recovery. I think Case No. 2 goes a long way in support of this view. So far as I can ascertain, the evacuation of eight pints of pus at one sitting is a record performance in a case of empyema.

I am, Sir, yours faithfully,

J. CÆSAR, F.R.C.S.I.

Minster, Sheerness, Feb. 25th, 1926.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 20TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 242 (last week 252); scarlet fever, 1825; diphtheria, 1165; enteric fever, 29; pneumonia, 1229; puerperal fever, 53; cerebro-spinal fever, 9; acute poliomyelitis, 2; encephalitis lethargica, 46; dysentery, 3; ophthalmia neonatorum, 99. There were no cases of cholera, plague, or typhus notified during the week.

*Deaths.*—In the aggregate of great towns, including London, there were 3 (1) deaths from enteric fever; none from small-pox; 116 (61) from measles; 13 (3) from scarlet fever; 65 (2) from whooping-cough; 50 (14) from diphtheria; 50 (9) from diarrhœa and enteritis under 2 years of age; and 76 (12) from influenza. The figures in parentheses are those for London itself.

**ROYAL MANCHESTER CHILDREN'S HOSPITAL.**—The ninety-sixth annual report shows that the management is faced with a heavy deficit (apart from the fact that £5020 is required for the new nurses' home), and this in spite of the fact that the ordinary income has been increased during the past few years. This implies the curtailment of valuable and necessary work and development. During the past year, as an experiment, accommodation has been provided for four private patients at fees ranging from 4 to 6 guineas a week. The arrangement does not reduce the number of ordinary beds and cots available, and it is thought that it may prove of benefit to many who are unable to pay heavy private nursing home fees, but wish to meet the full cost of hospital treatment. There was an increase in the number of patients treated during the year and also a marked decrease in the death-rate of the patients. A larger room and more lamps are to be provided for artificial sunlight treatment.

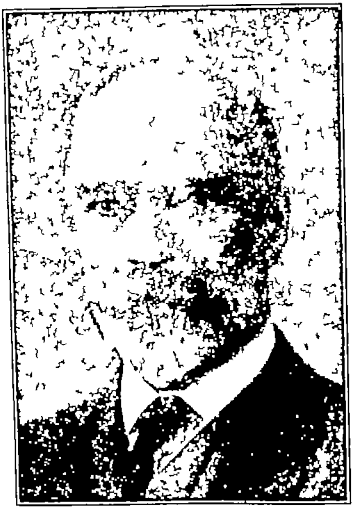
# Obituary.

## ARTHUR ROBERTSON CUSHNY, M.D. EDIN., M.A., LL.D. ABERD., F.R.S.,

PROFESSOR OF MATERIA MEDICA AND PHARMACOLOGY IN THE UNIVERSITY OF EDINBURGH.

By the death of Prof. A. R. Cushny the medical world loses an outstanding member, for he was a scientific authority of the highest reputation with much admirable and valuable research to his credit.

Born in 1866 at Speymouth, Morayshire, Arthur Robertson Cushny was the fourth son of the late Rev. John Cushny. He was educated in Aberdeen University, graduated M.A. in 1886 and M.B., C.M. in 1889, in which year he was the Thomson Fellow, and proceeded to the M.D. three years later. Thereupon he studied at Berne and Strassburg, and at the German University was appointed assistant to the professor of pharmacology in 1892–93. In the latter year he was elected professor of pharmacology in the University of Michigan, Ann Arbor, U.S.A., which post he retained till 1905, when he returned to this country on his appointment to the chair of Materia Medica and Pharmacology in the University of London. In London he remained till 1918, when he went to Edinburgh to succeed Sir Thomas Fraser. At Edinburgh he made considerable changes in his department, setting up an experimental laboratory and embarking with enthusiasm upon plans for the development of physiological research in its relations to pharmacology. These were in full development at the time of his sudden death.



PROF. A. R. CUSHNY.

(Photograph by Moffat, Edinburgh.

The life work of a scientist may be considered under three aspects. First, the actual additions to knowledge made by him; secondly, his power to inspire in others a love of research and to direct the energy thus aroused along profitable channels; and thirdly, the influence he has on the general development of his science. Prof. Cushny had an important influence on English medical science in all of these respects. First, the contributions which he made to the knowledge of pharmacology were invaluable, for he was one of the first to analyse the mode of action of digitalis on the heart. After establishing the general principles by animal experiments, he, in collaboration with his friend the late Sir James Mackenzie, carried out a series of observations on patients and showed the effect of the drug on the diseased heart. This fundamental work formed the basis for many of the important researches of Sir Thomas Lewis and others, who have during the past decade thrown so much light on the nature of heart disease. Prof. Cushny's work on diuretics also was notable, and in his monograph on the function of the kidney he brought forward the first coherent theory as to the mode of action of the kidney which at all accords with our modern knowledge of physical chemistry. Secondly, Prof. Cushny both in London and in Edinburgh showed that he had the power of inspiring research by others, and a number of the assistants whom he trained now hold posts in various parts of the Empire. He was a splendid trainer for young research workers, for he had an encyclopædic knowledge of his subject and also a very remarkable power of balanced judgment; to work under him was an education in accurate and scientific thought. Thirdly, the most significant aspect of Prof. Cushny's life work was the profound influence which he had on the development of pharmacology in this country. Unlike bacteriology, pharmacology did not start with a clear field, for our conceptions of the actions of drugs were (and are) distorted by all sorts of clinical traditions, some of them of great value and others mere relics of mediæval superstition. In the case of new drugs the search for the truth is hampered by the uncritical enthusiasm of those who are always seeking some new thing, and sometimes by commercial interests. Prof. Cushny's text-book, "Pharmacology and Therapeutics and the Action of Drugs," was the first comprehensive text-book of pharmacology to be published, and now in its eighth edition it is generally recognised as the most trustworthy and authoritative general text-book of its subject. It has had a profound influence on the development of pharmacology in this country and in America, for the author is severely critical, and has treated his subject as an exact science, refusing to admit as fact tradition unsupported by scientific evidence. This rigorous attitude, because it was based on wide knowledge and supported by an excellent power of judgment, has been of the greatest service to the science of pharmacology in its growth in difficult surroundings. His whole influence was directed towards making pharmacology an exact experimental science, which could serve as a secure foundation for the art of therapeutics. His work on digitalis, in which he first determined the fundamental principles by experiment and later applied this knowledge to clinical practice, is a model of the relation that he conceived should exist between pharmacology and therapeutics, but he always insisted that the essential duty of the pharmacologist was to get his data exactly correct, not permitting himself to be influenced by preconceived ideas as to what a drug was supposed to do.

Cushny was a frequent contributor to scientific literature, and we have great reason to be grateful to him at THE LANCET. Latterly he was joint editor of the *Journal of Pharmacology and Experimental Therapeutics*, and his last written work will be found in a series of lectures which he gave in the summer of 1925 under the Charles E. Dohme Memorial Foundation before the Medical School of the Johns Hopkins University, Baltimore. His subject was the biological relations of optically isomeric substances, and these lectures are now in the press.

With such success as a teacher it was certain that his services would often be sought by educational boards, and at different times he examined in his subject at the Universities of Oxford, Cambridge, London, Manchester, and Leeds, and also at the Conjoint Board of the English Colleges and at the entrance tests for the Indian Medical Service. He sat, also, on the Royal Commission on Whisky and other Potable Spirits in 1908, a Government inquiry which was much needed at a time when the trade in whisky was developing in a way that made the introduction of cheaply produced spirit a threat to public health.

Prof. Cushny's untimely death is an irreparable loss to English medical science, for he was for many years the senior pharmacologist engaged in research work in this country, and his strong personality made him the natural leader of his fellow scientists. He was still producing research work of first-rate importance, and his advice was being sought in all matters of general policy. To the medical school of Edinburgh his death is a particular blow; he always aimed at fostering the true scientific spirit amongst his students, who one and all as they worked with him esteemed him personally and felt the value of his encouragement and help.

Prof. Cushny's death came with great suddenness. He arrived home from London the day before his death, was taken ill during the night, and passed away on Feb. 25th at his home, Peffermill House, Edinburgh. He is survived by his wife and one daughter.

We have received the following tribute from Prof. W. E. Dixon, of Cambridge:—

"Prof. A. R. Cushny at the time of his death was the outstanding figure in pharmacology in this country. He was essentially a wise man, a man to whom one never appealed in vain for a valid criticism or an astute and considered opinion not only on all that pertained to the subject of which he was master, but on general principles in medicine, on questions of policy of organisation and education. His early training and the momentum which carried him through life was first derived from Oswald Schiedeberg, the founder of modern pharmacology, to whom Cushny acted for a time as assistant, and to whom he dedicated the early editions of his text-book, 'Dem Meister vom Schüller gewidmet.' The present generation have little understanding of the sacrifices which men like Cushny made to pursue their ideal. Nowadays, men fitted for research can obtain an ample wage, but in those days £100 per annum was affluence and it is small wonder that the few like Cushny, who for a time survive. leave a mark on history which is ineradicable. It was in Strassburg that his interest in cardiac irregularities and digitalis began, an interest which never ceased throughout life and which culminated in his book on digitalis published but recently. He first produced in animals the condition of auricular fibrillation and suggested that it was an unrecognised condition from which patients might suffer, but it was not till many years later that the condition was discovered in patients. His book on digitalis is essentially a description of the mechanism of the action of the drug on the mammalian heart; it is too modest in that, in his desire to be fair, Cushny lays too much stress on the work of other investigators, whilst the most valuable observations are those which were made or instigated by Cushny himself. Another great interest of Cushny throughout life was that of the kidney; he wrote many papers and finally a book on the subject. It is interesting to note that in one of his last papers he gave evidence for believing that caffeine acts as a diuretic by rendering the kidney more permeable to water just as phloridzin acts by making it more permeable to sugar, or phenyl carboxylic acid (atophan) by rendering it more permeable to uric acid. Another subject to which he gave a great deal of attention was the question of optically active isomers. He showed, for example, that the early specimens of synthetic adrenalin had only half the activity of the natural product, because the natural product con- [illegible] of the lævo-variety, whereas the synthetic substance was a mixture of equal parts of the two varieties. His experiments were continued with the hyoscyamines, hyoscines, nicotines, &c., in each case the activity occurring in only one isomer. Besides these he had many minor papers of interest; thus he drew attention to the convulsant action of the common nutmeg and showed that certain outbreaks of cirrhosis of the liver in cattle were due to senecio, a variety of groundsel.

"Cushny was a pioneer, he gave himself to pharmacology when it could not be said to exist in this country, long before it was known that the internal secretions largely governed the body's activity by means of alkaloidal-like substances. His work mainly consisted in investigating the mode of action of drugs, but his interest in the patient never ceased and in some of his researches he was associated with clinicians, the late Sir James Mackenzie, and others. Prof. Cushny just before his death was taking an active part for a reformed British Pharmacopœia; he regarded the Pharmacopœia as being edited on an entirely wrong principle which had tended to stereotype therapeutics on the lines of obsolete tradition with a resulting expenditure of money by the public on drugs of little or no value. Prof. Cushny possessed a great personality; it was only necessary to be with him to experience his wonderful charm and to understand how he inspired in his friends and pupils alike confidence and affection. It was to no small extent these qualities which enabled him to build a school of experimental pharmacology in Edinburgh. Cushny was a scholar, a teacher, and the best and most steadfast of friends; he passes to posterity as a pioneer of the science which he did so much to make, and leaves a great record of work of fundamental importance."

## JOHN CAMERON YOUNG, M.D. Glasg.

The death in Abyssinia of Dr. John Young, of Aden, closes the career of a great Scottish missionary. He had spent 32 years of his life in one of the most trying climates in the world. Yet he never spared himself and was never long off duty. From childhood he had learnt the meaning of hard work, for at the age of 10 he had to leave school to help earn his living. A few years later he was apprenticed to a joiner, and it was whilst working at this trade that he went through a religious experience which led him to attempt greater things. He made up his mind to be a missionary, and kept himself by vacation and evening work whilst studying medicine, arts, and theology at the University of Glasgow. Graduating as M.B., C.M. in 1882, he was appointed by the Free Church of Scotland to the mission of Sheikh Othman near Aden. Here he had to train his own staff of assistants—anæsthetist, dispenser, dresser—and for many years worked under great difficulties. In 1909 a hospital with nominally 100 beds was completed, the money for which he mainly raised himself; but soon this proved too small. Patients flocked from all parts of Southern Arabia and the annual list of operations mounted to more than 2000. Yet medical work was only part of Young's activities. At one time he took charge of the school, and some of his Arabian pupils distinguished themselves in after-life, though not many were converts. He acted as chaplain to the Presbyterian and Wesleyan troops of the Aden garrison, and during the war took charge of the European General Hospital, and was port health officer. "He was 'always a fighter,'" writes a colleague, "fighting the battles of the oppressed and helpless, fighting ignorance and disease, bad customs and habits, wrong beliefs. He was generous to a fault, sometimes overwhelmingly so, and no one had a kinder heart. In almost every country of the globe there are many who feel the world is poorer since John Young passed to his rest." Dr. Young was on holiday in Abyssinia for his health's sake when he died. But even there he was engaged in the work he loved, and he died, as he had wished, in harness.

# Parliamentary Intelligence.

## HOUSE OF COMMONS.

### Tuesday, Feb. 23rd.

### *War Pensions Administration.*

Mr. Walsh called attention to war pensions administration, and moved "That a select committee be appointed to inquire into the general administration and practice of the Ministry of Pensions, with special reference to the questions of final and erroneous awards, parents', dependants', and widows' pensions, the regulations governing the appointment and powers of area war pensions committees, advisory councils, regional officers, and special grants committees, the seven years' limit for claims in respect of pensions for death or disability due to war service, and the advisability of appointing an independent court of medical appeal for the hearing of appeals against decisions of the entitlement and assessment appeals tribunals." He said he would like to suggest the appointment of an independent medical tribunal to take into consideration, free from all prejudice, free from all predilections, free as far as possible from all knowledge of what had gone before, the cases that have been submitted against the entitlement and assessment appeal tribunals. Like other Members he had had a good many cases submitted to him, and in the big majority he had found nothing but fair treatment from the Department, whoever had been the Minister at the time, but there had been many cases where men complained that the doctor who was upon the assessment tribunal and the doctor who attended upon the entitlement tribunal was the same doctor who sat daily on their appeal tribunal.

Lieut.-Colonel Pownall moved the following amendment "That, having regard to the prolonged consideration of all aspects of pensions administration in connexion with the Great War which has been given by select and other committees of inquiry and by this House itself, it would, in the opinion of this House, be undesirable that the settled fundamental principles of war pensions administration embodied in Royal Warrant and statute, which have been maintained by successive Parliaments and Governments in recent years, should be reopened and be again made the subject of formal inquiry by a select committee of this House." He said that by the proposal of Mr. Walsh they would upset the whole of the pensions administration, although the late Minister of Pensions had admitted that 85 per cent. of the cases were well met by the existing laws or regulations. The motion would raise false hopes in thousands and tens of thousands, and it might be hundreds of thousands, of those whose claims had been fully investigated by the Pensions Appeal Tribunal This seemed to him to be very unfair What the country wanted was not a select committee of inquiry; what was wanted now was security and stability. He would welcome a decision to stabilise the present rates for a further period of three years, and it might well be for another period after that. He would like to see the number of medical boards reduced.

Colonel Clifton Brown seconded the amendment. As regards the medical boards no pressure in his experience was exercised on any doctor. When they were closing down cases, hard cases must arise, and the Ministry of Pensions, so far as he had followed its operations, had very wisely brought in a system of correction of errors. Any man who got worse was entitled to medical attention, and if it was found that any real mistake had been made—and he did not think that there were so many as some people thought—the error was corrected and the subsequent pension was adjusted to the state of health which the man had then reached. They must remember what wide effects the appointment of a select committee would have on ex-Service men throughout the country. There was no end to the time which it would occupy and no end to the number of cases which would be held up. As an ex-Service man who had spent three very happy years at the Ministry of Pensions, he thought that nothing could be more damaging to the interests of his fellow ex Service men at the moment and to the whole administration of pensions than the appointment of a select committee. He hoped the House would resist the motion.

Major Cohen said it seemed to him rather a terrible thing that seven years after the war ended, when they were all satisfied that at any rate some ex-Service men were not getting all they ought to get, the House of Commons should be forced to a party division on a matter of this kind. It seemed to him that they wanted a little of the Locarno spirit in the House of Commons. He asked the Minister if he could not see his way to grant a select committee, at any rate to deal more generously and more kindly with the representative body of ex-Service men—he meant the British Legion. Very reluctantly he felt he must vote against the Government.

Mr. Ellis Davies referred to the question of medical tribunals, and in particular appeal tribunals. It was essential that the gentlemen who, though members of the medical profession had, in fact, become Government officials, should not have the determining voice with regard to these pensions. He spoke with some experience of the Workmen's Compensation Act, and there were two diseases in which a good many mistakes were made—nervous disorder and heart disease. They were the two diseases of which the medical profession was at present most uncertain. Anyone who had to consult even a leading practitioner in London on either of those two diseases would be informed by those high authorities that with regard to nervous disorders and heart disease they were practically at sea even at the present day. These were the cases out of which most of the complaints with regard to medical tribunals arose. All these things showed the necessity for a thorough investigation into the conditions under which pensions were awarded.

Dr. Drummond Shiels said he found himself very much in sympathy with the remarks of Mr. Ellis Davies. The whole pensions system penalised the man who was plucky, the man who did not run to the field ambulance or the hospital on every occasion. A man might have worked, as many did, with heavy colds or chest complaints for months. He carried on and there was no entry in his medical sheet. He ultimately developed tuberculosis. His medical sheet was turned up and he was told "This was not contracted in the war because there is no record of your having been to the hospital with pleurisy or anything else." He wanted to put in a word for tuberculous ex-Service men who were not very satisfactorily treated in some ways. He put in a plea for the special diet allowance which they had some years ago. He supported the motion for a select committee.

Major Tryon (Minister of Pensions), replying to the debate, said that the overwhelming mass of corrections of errors took place through the normal channel; they were corrected when the men came up for treatment. There had been inquiry after inquiry and committee after committee, but the objection to upsetting all the work of the Pensions Department was that they could not now reopen all these questions. They could not change the system of compensation according to the extent of disablement to a system of final awards If it was decided to appoint a select committee they would have to stop at once the granting of final pensions to a large number of men who to-day were passing from the realms of anxiety and uncertainty to the knowledge that their assessment was assured They were not prepared to leave the matter to the risk of a select committee. It was not the policy of a Ministry to stand still All through it had been the Ministry which had taken the initiative in reforms. It was the Ministry which introduced the Correction of Errors Board on their own initiative. They wanted to settle this question amicably and to give security to the pensioner To give him that security they had stabilised his rates.

On a division the motion for the appointment of a select committee was rejected by 250 votes to 151. It being after 11 o'clock the debate on the amendment was "talked out."

### Wednesday, Feb. 24th.

### *Ministry of Pensions Vote.*

The House went into Committee of Supply on a vote of £1,192,000 for the salaries and expenses of the Ministry of Pensions, Mr James Hope in the chair.

Lieut.-Colonel Stanley (Parliamentary Secretary to the Ministry of Pensions) said that medical treatment, medical assessment of the disabled, the admission of claims, and the award of pensions, had proceeded without hindrance in accordance with the criteria laid down in the Royal Warrants, and if the cost had amounted to more than was estimated, the ex-Service men and their dependants had benefited. He thought that they were getting much nearer to accuracy of prognosis, but it was quite impossible to foretell with accuracy the operation during the year of very diverse factors. It was inevitable that a substantial minority of cases should still be found to be suffering from conditions that refused to yield to treatment, and that in some instances there should be a gradual deterioration. He referred in the main to the men suffering from such diseases as tuberculosis, chronic cases of acute bronchitis, organic heart disease, and paralysis. In such cases where a man was examined and found to be worse his pension had to be increased. But there was a very considerable off-set due to death and other causes. There was a large number of serious cases which must be provided for in hospitals, and some cases would always have to be so provided for. The excess expenditure on medical treatment was due entirely to the cost of treatment in hospitals being greater than was expected. The expenditure on other forms of treatment had declined. The number of out-patients during the past year had decreased, and that was a continuation of a process which had been going on for three years. There was also a decrease in the work of the medical examination of pensioners consequent on the increased stability of pensions. As a result there were fewer doctors employed, and fewer men had to travel to the medical boards. This meant a decrease on the score of expenses.

Mr. SPENCER said that from his experience of medical boards he should have been very pleased to find that sub-head of the vote swept away. In his opinion the medical boards had been a discredit to the Ministry and were among the worst institutions that had been set up. He knew of no body of men who differed more in their opinions regarding cases than the medical profession. The only board which could justly meet the requirements of all the people concerned would be a board in which the final decision was not given by medical men, but by some legal person who could weigh evidence after medical evidence had been given on both sides.

Dr. VERNON DAVIES said he was astonished to hear Mr. Spencer make such statements about the medical boards. He thought it was not in the interest of the pensioners to make them dissatisfied with the medical referees who were judging these cases. The hon. Member seemed quite prepared to accept the certificate of a panel practitioner, but when the same doctor was acting as a medical referee on behalf of the Ministry he seemed to think that the certificate must be wrong. Possibly it was wrong; doctors differed and disagreed, and when it came to an interpretation each man was entitled to his own opinion. But hon. Members who created dissatisfaction in the minds of the public with the decisions of these medical men were doing the pensioners a great disservice. Since the war a new state of mind had developed. If a man developed rheumatism six or seven years after war service it was said that that rheumatism must be due to war service; but people who had not been to the war developed rheumatism. Hon. Members should give medical men the credit for being honest in their opinions, and should try to convince the country that there were diseases with which the war had no connexion. Under the heading of Medical Treatment of Disabled Officers, Nurses, and Men, he noticed that the Minister was asking for an additional £216,000 which was roughly 10 per cent. of the original estimate. He should like a little more information why there had been this increase. One class of cases in which the Ministry might extend their efforts were the neurasthenia cases, which were becoming more and more troublesome and in some cases there were definite hardships.

Major TRYON (Minister of Pensions), replying to the debate, said that Dr. Vernon Davies had put the medical point of view in a speech which was of very great value, because it showed not only how difficult was the task of medical officers to deal with these questions, but it also brought home to the committee the obvious desire of the whole medical profession to deal fairly with cases of assessment and with pensions questions generally.

The vote was agreed to.

### *Tuberculosis in the Navy.*

Sir BERTRAM FALLE asked the Parliamentary Secretary to the Admiralty the number of naval ratings who were invalided during the period Jan. 1st to Dec. 31st, 1925, with tuberculosis; and how many of the cases were considered to be attributable to service.—Mr. DAVIDSON replied: The total number of ratings invalided for tuberculosis in 1925 was 217; of these, three were found to be attributable to the Service.

### *Hospital Accommodation at Sarafand.*

Mr. DAY asked the Secretary of State for Air whether the unsatisfactory hospital accommodation at Sarafand had yet been remedied, and in what manner.—Sir S. HOARE replied: The difficulties of hospital accommodation are being overcome by the conversion of existing buildings at Sarafand into a new hospital; the work is due for completion by March 31st next.

### *British Medical Association and Colonial Medical Appointments.*

Mr. DAY asked the Secretary of State for the Colonies if he was aware of the manifesto issued by the British Medical Association in regard to the acceptance by doctors of colonial appointments; and whether he would reconsider the new regulations with a view to consultation with the Association.—Mr. AMERY replied: I have seen this announcement which arises out of regulations recently issued for the East African Medical Service, and which was published before I had had an opportunity of considering the representations which members of the medical staff in East Africa wished to make to me as to the effect of these regulations on officers already in the Service. I have now received and considered these representations and have reached certain decisions with regard to the points raised. I have intimated to the British Medical Association that I am prepared to receive a deputation from them.

## THURSDAY, FEB. 25TH.

### *Miners and Nystagmus.*

Mr. SPENCER asked the Home Secretary whether he was aware that nystagmus was on the increase among coal-miners; [illegible]her he intended to give effect to the recommendation of the Medical Research Committee with regard to a higher standard of illumination by making it compulsory to provide the same.—Colonel LANE-FOX replied: The incidence of miners' nystagmus is still very heavy, but the total number of cases in 1924 was slightly less than in 1923; the number of new cases declined both in 1923 and 1924, and I hope will continue to do so. I expect before long to be able to fix a higher candle-power standard for flame safety-lamps. As regards electric safety-lamps, the present standard of candle-power is much higher than the standard for flame lamps, and I am advised that it is not yet practicable to raise it.

### *Death Certification.*

Mr. DAY asked the Minister of Health if he would consider amendment to the Death Certification Act, so as to cause the compulsory examination of the body before a death certificate was issued by a medical practitioner.—Mr. NEVILLE CHAMBERLAIN replied: The subject of death certificates is already under my consideration with other related questions, but I cannot see my way in present circumstances to introduce any legislation.

### *Lunacy Reform Report.*

Mr. DAY asked the Minister of Health when the Royal Commission on Lunacy Reform was likely to make its report.—Sir W. JOYNSON-HICKS replied: I understand that the Royal Commission hope to be able to present their report this summer, but it is not possible at present to give the precise date.

### *Grade A Milk and Pasteurised Milk.*

Lieut.-Colonel FREMANTLE asked the Minister of Health the number of producers holding licences to sell Certified Grade A (tuberculin tested) and Grade A milk respectively; and the number of cows whose product was sold under each designation, respectively.—Mr. NEVILLE CHAMBERLAIN replied: The numbers of producers' licences for Certified and Grade A (tuberculin tested) milk in operation in England and Wales at the present time are 96 and 97 respectively. The number of such licences for Grade A milk on March 31st, 1925 (the latest date for which figures are available) was returned as 110. The numbers of cows in the herds producing the first two grades of milk are approximately 3500 and 3600 respectively. No precise information is available as to Grade A herds, but I am advised that the number of cows in such herds may be roughly estimated at 2000 to 2500.

Colonel FREMANTLE asked the Minister of Health the number of firms or persons licensed to sell pasteurised milk and the estimated quantity sold annually of such milk.—Mr. NEVILLE CHAMBERLAIN replied: Licences for the sale of pasteurised milk are issued by local authorities. The latest available returns are those of licences in force on March 31st, 1925, and they give the number of pasteurising establishments as 62 and of other premises licensed to distribute as 370. I have not complete information as to the total quantity of milk which is being sold in England and Wales at the present time as pasteurised, but I am advised that, on a rough estimate, it may be taken to be between 15 and 20 million gallons per annum.

### *Bovine Tuberculosis and Man.*

Colonel FREMANTLE asked the Minister of Health if he had evidence that bovine tuberculosis is communicable to man by the consumption of tuberculous milk.—Mr. NEVILLE CHAMBERLAIN replied: Yes, Sir. I am advised that the positive conclusions of the Royal Commission on Tuberculosis on this subject have been confirmed by the subsequent work of many investigators at home and abroad.

### *Remuneration of Panel Practitioners.*

Lieut.-Commander KENWORTHY asked the Minister of Health whether the remuneration withheld from insurance practitioners under the powers in that behalf contained in the National Health Insurance (Medical Benefit) Regulations, remained in the central fund for eventual distribution amongst insurance practitioners, or whether it was applied in any other direction; and, in the latter case, how it was dealt with.—Mr. NEVILLE CHAMBERLAIN replied: Sums withheld from insurance practitioners in the circumstances referred to are not returned to the central pool for distribution among practitioners, but are carried to a special fund from which, under Article 21 (2) of the regulations cited, payments are made to insurance committees towards meeting exceptional expenses incurred by them in the administration of medical benefit.

### *Blind Persons.*

Mr. FRANK LEE asked the Minister of Health if he could give the number of blind persons in England, Scotland, and Wales; how many of these were between the ages of 50 and 70 years and receiving State pensions; how many councils, county or borough, had established workshops for the blind in their area; and how many persons were being trained or being found work therein.—Mr. NEVILLE CHAMBERLAIN replied: The number of blind persons in England and Wales on March 31st, 1925, was returned as 42,110. Of these 16,018 were between the ages of 60 and 70, of whom 12,872 were on Sept. 30th last in receipt of pensions under Section 1 of the Blind Persons Act, 1920. Only three local authorities in England and Wales have found it necessary to establish workshops under this Act, providing employment for 23 blind persons, while the remainder of the local authorities contribute towards the workshops established by voluntary agencies which provide employment for 2200 blind persons.

### *Medical Officers and Cold Storage.*

Mr. SPOOR asked the Minister of Health whether, in view of the situation about to be created by the prohibition of food preservatives, he would call for a return from medical officers of health indicating the extent, adequacy or otherwise of cold storage in their respective area; and what steps the Ministry proposed to take to encourage the use of refrigerators in the homes of consumers.—Mr. NEVILLE CHAMBERLAIN replied: I do not think it necessary to call for such a return as the hon. Member suggests, since information as to the cold storage accommodation of the country is already in the possession of the Government. As regards the second part of the question, I think that the hon. Member probably overestimates the extent to which the Preservatives Regulations will necessitate any increase in the facilities for domestic refrigeration in the home, and I do not propose to take any steps in the matter.

### *Insured Persons and Optical Benefit.*

Mr. VIANT asked the Minister of Health (1) if he was aware that the proportion of refraction cases referred by some panel practitioners to ophthalmic surgeons was extraordinarily high, while the number so referred by other panel practitioners was exceedingly low; and whether he would issue instructions to such practitioners which would insure greater uniformity; and (2) if he was aware that many cases of refraction, where no ocular disease existed, were being referred to ophthalmic surgeons, thereby seriously depleting the surplus funds of approved societies unnecessarily; and if he would make regulations limiting the cases in which reference to ophthalmic surgeons was permitted.—Mr. NEVILLE CHAMBERLAIN replied: It is no part of the duty of an insurance practitioner to refer applicants for ophthalmic benefit to ophthalmic surgeons, but where the practitioner is of opinion that a patient is in need of ophthalmic treatment or optical appliances he gives him, if desired, a written recommendation to be forwarded to his approved society. It then rests with the society to decide whether the application for ophthalmic benefit is to be granted, and, if so, whether the payment that they will make is to cover the cost of examination or treatment by an ophthalmic surgeon. I know of no good reason for seeking to limit the discretion of societies in the manner suggested, and in any event I have at present no power to make regulations for such a purpose.

Mr. DAY asked if the Minister of Health would seek the powers that were necessary

Sir K. WOOD: No, Sir. I have just said that it is thought better, at any rate at present, to keep the matter in the discretion of the approved societies.

Mr. RHYS DAVIES: Is the hon. gentleman not aware that the approved societies have no power to act in the way he has suggested, and in view of the fact that the Ministry of Health has no power to deal with the difficulty, will the Minister seek new powers?

Sir K. WOOD: I cannot agree with the hon. gentleman. I know that he has a great deal of knowledge upon this matter, but we are certainly advised that the approved societies themselves have the determination of this matter and are constantly doing so.

Mr. COMPTON: Is the hon gentleman aware that the State auditors of the Department refused to sanction payments unless the medical certificate is produced in the first instance and the approved societies have no discretion in the matter?

Dr. VERNON DAVIES: Are we to understand that the approved societies consult the ophthalmic surgeons or the doctor in charge of the case?

Sir K. WOOD: I think it is generally done by consultation between the approved society and the doctor on the panel.

### *Small-pox in Durham.*

Mr. WHITELEY asked the Minister of Health the number of notifications of small-pox in Durham county during the last four weeks; whether the necessary loans applied for had been granted in order to provide the essential equipment and staff to deal effectively with the cases; and whether there was any abatement of the epidemic.—Mr. NEVILLE CHAMBERLAIN replied: 905 cases of small-pox were notified in the county of Durham during the four weeks ended Feb. 20th. The application received from the county council for sanction to a loan is now under consideration. Fewer cases were notified last week than in any of the previous six weeks, but I am afraid that at present there are no signs of any substantial abatement of the epidemic.

### *Tuberculosis in the Air Force.*

Dr. VERNON DAVIES asked the Secretary of State for Air if he had formed any opinion as to how the conditions of service had caused or contributed to the disease of pulmonary tuberculosis in the 17 officers and men who had been invalided out of the Service during the last three years for which records were available which had been decided as attributable to the conditions of service; if pensions had been granted these officers and men on account of their disability; and, if not, what compensation had been given them.—Sir S. HOARE replied: In answer to the first part of the question, it would not be practicable to state in general terms or otherwise than by detailed explanation of case by case to what conditions of Service the disabilities of the 17 officers and men referred to were attributable. Analysis of the cases, eight of which were attributable to service in the war, has failed to reveal any particular condition of service which can be regarded as a common causal or contributory factor. As regards the remaining parts of the question, in 16 cases pensions have already been awarded; the remaining case is under consideration.

### *Deaths from Small-pox.*

Mr. SCRYMGEOUR asked the Minister of Health how many cases of small pox had been notified in the country for the year 1925; how many deaths from small-pox had been registered; and whether any other cause of disease helped to cause the death in the fatal cases.—Mr. NEVILLE CHAMBERLAIN replied: 5363 cases of small pox were notified in England and Wales during 1925, but this figure is subject to revision. Of the 9 deaths registered in which small-pox was entered on the death certificates, death was attributed solely to small-pox in three cases, while in the remaining six cases other causes were also entered on the death certificates.

## FRIDAY, FEB. 26TH.

### *Births and Deaths Registration Bill.*

Mr. TINNE, in moving the second reading of the Births and Deaths Registration Bill, said its object was to make more complete and effective the safeguards afforded by the law of registration in relation to the disposal of the dead with a view to eliminating as far as possible any risk or opportunity for the concealment of crime. Provision was made enabling local authorities to arrange in certain instances for the medical inspection of the body of a dead person and for regulating certain means of disposal. The Bill required still-births to be registered as an additional safeguard to infant life. An attempt had been made to remove one of the objections raised against previous Bills by eliminating the clause as to the universal medical inspection of bodies for burial. The new clause made it lawful for a county council, a county borough council, the Common Council of the City of London, or a metropolitan borough council, with the approval of the Minister of Health, to make arrangements that where a body had not been seen by a registered medical practitioner since death, the services of a registered medical pactitioner should be made available for verifying at the request of the coroner the death of anybody dying within the coroner's jurisdiction. The Bill contained nothing that was really controversial.

Lieut.-Colonel FREMANTLE traced the previous Parliamentary history of the subject, and said that the committee in 1893 recorded their conclusion that uncertified deaths should, as a class, cease to exist, and that means should be devised whereby a medical certificate should be obtained in every case. A Departmental Committee on the Law relating to Coroners reported in 1909 that the existing law as to death certification offered every opportunity of premature burial and every facility for the concealment of crime; that medical practitioners might certify merely on the information given by relatives; and that there was evidence that in many cases these certificates were carelessly and even recklessly given. Over and over again it had been shown that the cause of death was not completely notified in the certificate and that certificates gave a very inexact cause of death. Such a state of matters was dangerous from the point of view of possible carelessness giving shelter to crime and from the point of view of those who wanted to make those scientific statistics of disease from which so large an amount of legislation and administration was derived. For both reasons it was necessary to try to improve the certification of the cause of death. Each of the previous Bills with which he had been associated contained proposals that every death should be verified by a certificate from a medical man who had inspected the body after death. The proposal was unnecessary from the point of view of the dead person or the relatives, and the cost would fall on public funds. The only way was to trust the medical man. In at least 900 cases out of 1000 the medical man did all that was necessary.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) commended the Bill to the favourable consideration of the House. The Bill, he said, would put an end to all irregularities under the present system. It contained good machinery for preventing the surreptitious burial of a body under an authority which related to another body. A very important matter was that of still-births in which connexion a good deal of reform was needed. The requirement of the Bill that all such births should be registered would, he hoped, do much to prevent improper practices. The measure was a useful one, but it would need careful examination in committee.

Major-General Sir R. Luce said that though fully agreeing with the objects of the Bill which were in every way commendable, it did not seem to him that the Bill had the merit of doing very much towards carrying out the objects it had in view. The chief object of the Bill should be to prevent any person being buried without proper knowledge of the immediate cause of death being available. Two reasons had been referred to. One was the prevention of crime and the other was the prevention of premature burial. The methods in the Bill to secure these objects seemed to him totally inadequate. For a long time there had been a general body of feeling that it was absolutely essential to prevent those things, that there should be a compulsory view of the body after death and before burial by a qualified person, but the method suggested in the Bill seemed totally inadequate. What was wanted was some method by which a body could be examined so as to certify that it was dead and that there was no obviously violent cause of death. No attempt had been made in this case to utilise the most valuable opportunity presented by the Bill to increase the scientific knowledge of the cause of death. It was quite true that in many cases the medical man did not give an absolutely complete account of the cause of death owing to his desire not to hurt the feelings of the relations. The only method suggested here to get over that difficulty was that the certificate should in future be sent direct to the registrar, but it would be the duty of the registrar as at present, if the relatives asked for it, to send them a copy of the certificate, so that there would be no difference made to the medical man and there would be no confidential relations between him and the registrar any more than at present. There was another omission in the Bill and that was the question of the relations of the medical practitioner and the coroner in cases in which there was a certain doubt as to the cause of death, or in which there was some question of violence or accident. There ought to be either in this Bill or in the Coroners Bill, which was already in the House of Lords, some arrangement by which it was definitely stated that in cases of doubt on the part of the medical man as to the cause of death, or in cases where he believed the death was due to violence or accident, it should be his duty to inform the coroner in order that the coroner might at once take up the case. In these cases it should not be the duty of the medical man to give a certificate of death, but the duty of the coroner. Perhaps many of these points were very difficult to get over without raising the question of expenditure of money. It was undoubted that if the medical man had to visit in all cases the body after death he would have to be paid to do so. If that were so, he quite realised that it would be difficult to get any amendment of the Bill that would produce these effects, which he thought were absolutely essential to any improvement in the Registration Act. At the same time, as these objects were partially brought forward in this Bill and in so far as he hoped it might not prejudice a more complete Bill in the future, he did not propose actually to oppose the Second Reading.

After further discussion the Bill was read a second time without a division.

### Monday, March 1st.

### *Cost of Patients in Sanatoria.*

Mr. Naylor asked the Minister of Health the average weekly cost per patient, including maintenance, medicines, medical attendance, laundry, &c., in sanatoria controlled by local authorities or other institutions recognised by his department.—Mr. N. Chamberlain replied: The average weekly cost per patient in institutions approved by my department for the treatment of tuberculosis was 49*s.* 4*d.* during the year ended March 31st, 1924, which is the last year for which complete figures are at present available.

### *After-effects of Juvenile Encephalitis.*

Mr. Compton asked the Minister of Health whether any estimate could be given of the percentage of recoveries from juvenile encephalitis which had suffered mental or moral injury from that disease.—Mr. N. Chamberlain replied: I regret that at present there is not sufficient information available to enable such an estimate to be given.

### *League of Nations and Health.*

Mr. Groves asked the Minister of Health whether any report had been received by his department on the conference of members of the Health Committee of the League of Nations at The Hague on Jan. 4th to 7th; and whether the suggestions of the conference, as adopted, on the motion of Prof. Ricardo Jorge, would be carried out by his department.—Sir K. Wood replied: My right hon. friend has received the report of the British delegate, but the suggestions of the conference have not yet been transmitted by the Health Committee of the League of Nations. As soon as these suggestions are received they will be referred for consideration to the Committee on Vaccination which was recently appointed.

### *Midwives and Maternity Homes Bill.*

The Midwives and Maternity Homes Bill was read a second time.

### Tuesday, March 2nd.

### *Encephalitis Lethargica.*

Mr. Ammon asked the Minister of Health whether the Government was inclined to view favourably the offer received from Dr. Damoglou to place at the disposal of his Ministry a method of treatment of cases of encephalitis lethargica.—Sir K. Wood replied: The answer is in the negative.

### *Nursing Homes Registration.*

On the motion of Colonel Gibbs (Treasurer of the Household) a Select Committee was appointed to consider and inquire into the question of the inspection and supervision of nursing homes and to report what legislation, if any, was necessary or desirable for the purpose. Sir Cyril Cobb, Dr. Vernon Davies, Sir Leolin Forestier-Walker, Colonel Hurst, Sir Richard Luce, Mrs. Philipson, Major Price, Dr. Salter, Miss Wilkinson, and Mr. C. H. Wilson were nominated members of the Committee.

## Medical News.

University of London.—A meeting of the Senate was held on Feb. 24th, Prof. E. A. Gardner, the Vice-Chancellor, being in the chair.—Prof. C. A. Lovatt Evans F.R.S., was appointed to the Jodrell Chair of Physiology tenable at University College. Since March, 1922, he has been University Professor of Physiology at St. Bartholomew's Hospital Medical College. During this period he published Recent Advances in Physiology (1925) and was editor of Bainbridge and Menzies' "Essentials of Physiology" (1925).—Dr. G. V. Anrep was appointed to the University Readership in Physiology tenable at University College. He was educated at the University of Dorpat and at the Medical Faculty of the University of Petrograd. From 1917–20 he was senior assistant in physiology at the Institute of Experimental Medicine of Petrograd, and in 1920 he was appointed assistant and in 1923 senior assistant in physiology at University College, London. He has been awarded the Schäfer Prize and the Julius Mickle Fellowship (1924–25) for his research work in this University. His published work includes numerous articles in the *Journal of Physiology* (1912–25), Proceedings of the Royal Society (1923–25), and in *Heart.*—The title of Emeritus Professor of Obstetric Medicine at University College was conferred on Dr. H. R. Spencer.—The following were appointed Fellows of University College: Mr. James Thornton Carter, Prof. H. B. Fantham, Mr. Morris Ginsberg, Prof. Yaroslav Heyrovsky (of Prague), Dr. A. G. Levy, and Mr. G. Udny Yule, F.R.S.—The following were appointed Fellows of King's College: Sir James Kingston Fowler and Prof. William Wilson, F.R.S.—Dr. H. L. Eason has been reappointed as the representative of the University on the General Medical Council.

Royal National Orthopædic Hospital.—A festival dinner in aid of the funds of this hospital was held at the Hotel Victoria, London, on Feb. 24th, when H.R.H. Prince Henry, the President of the institution, presided over a large gathering assembled to promote the fund for the provision of additional beds and of an extension of the out-patient department. Mr. Herbert West, chairman of the special committee appointed to organise the fund, stated that of the sum aimed at—namely, £87,500—£40,000 had already been received, with the result that the enlargement of the buildings in Great Portland-street was being undertaken, while it was hoped that, as further support came in, the first unit of the country branch at Brockley Hill could be proceeded with. Following on this statement Prince Henry, in proposing the toast of the hospital, pointed out the national importance of the work that it had already done since its foundation in 1838. At its central departments, both in-patient and out-patient in London, as also at its Stanmore branch in the country, the preventive and curative sides of orthopædic surgery were being steadily carried on, he said, by a medical staff which included many of the greatest names in orthopædic surgery. He laid stress on the need for the development of the country branch, because continuous treatment was necessary in those cases, while in the open air the children enjoyed "all the natural sunshine which our climate permitted." He outlined the extensive nature of the activities of the hospital and stated that the need for school education concurrent with surgical treatment had been fully recognised, for the hospital had schools both at Great Portland-street and at the country branch, which were staffed by fully qualified and certified teachers. He concluded a clear exposition of the labours and deserts of the institution by an acknowledgment of the sympathetic coöperation which had been obtained from health and education authorities, from infant welfare workers, and from Red Cross. The Spanish Ambassador, who supported the toast, drew an eloquent analogy between the action of Christian kings, queens, and princes in the middle ages in their fights for the Cross to the crusades against disease now regularly led in Europe, and especially in England and Spain, by the Royal Houses and their scions. Mr. Reginald McKenna, treasurer of the hospital, responded to the toast with an ingenious suggestion that donations to the hospital were really investments, and other speakers included the Earl of Denbigh, the Bishop of St. Albans, Major-General J. E. B. Seely, and Sir Squire Sprigge. At the conclusion of the proceedings Prince Henry announced that £7500 had been subscribed at the dinner.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On March 11th, at 5 P.M., in the lecture-room of the Medical Society, 11, Chandos-street, London, W., Colonel F. E. Fremantle will deliver a lecture on the Economics of Public Health. This lecture will be open to all members of the medical profession. On the same day, at 5 P.M., Mr. E. T. C. Milligan will give a special demonstration in clinical surgery at St. Mark's Hospital. This will be free to members of the Fellowship and holders of tickets for its general course. There will be a special course in gynæcology at the Chelsea Hospital for Women, beginning on March 8th and lasting for three weeks. Operations, lectures, and demonstrations will be given during the daily sessions. The daily afternoon demonstrations on the Diagnosis and Treatment of Diseases of the Eye continue throughout the week at the Royal Eye Hospital, beginning at 3 P.M. On March 15th the Hampstead General Hospital will begin an afternoon course (1.30–6) for the benefit of general practitioners. The daily sessions will include surgical and medical demonstrations and lectures, and the course will last for a fortnight. The London School of Tropical Medicine begins a series of eight clinical demonstrations on March 16th, which will continue for four weeks on Tuesdays and Thursdays at 2 P.M. Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

BRITISH PHARMACOPŒIA.—A conference took place on Feb. 23rd between the Pharmacopœia Committee of the General Medical Council and representatives of societies and public bodies interested in the revision of the Pharmacopœia. The following delegates were present: Dr. Smith Whitaker and Dr. A. W. Adams (Ministry of Health); Dr. H. H. Dale, F.R.S., and Lieut.-Colonel Sir David Prain, F.R.S. (Royal Society); Sir W. Hale-White and Prof. A. J. Clark (Royal Society of Medicine); Prof. T. R. Elliott, F.R.S., and Sir Walter Fletcher, F.R.S. (Medical Research Council); Dr. E. Lewis Lilley and Dr. J. W. Bone (British Medical Association); Mr. P. F. Rowsell and Mr. Edmond White (Pharmaceutical Society); Prof. A. R. Cushny, F.R.S. (since deceased), and Prof. W. E. Dixon, F.R.S. (Physiological Society); Prof. F. G. Donnan, F.R.S. (Chemical Society); Mr. A. B. Rendle, F.R.S., and Dr. A. T. Gage (Linnean Society); Mr. H. Todd and Mr. W. J. Hardy (Northern Ireland Pharmaceutical Society); Mr. G. A. McLean Lee and Mr. J. Smith (Southern Ireland Pharmaceutical Society); Mr. A. C. Chapman, F.R.S., and Mr. E. Hinks (Society of Public Analysts). The President outlined the history of the past issues of the British Pharmacopœia, and the present position as regards its revision. He mentioned that the Dominion of Canada had made a suggestion which might result in arrangements being made for the fuller consideration of special Canadian requirements, and said that it was probable that if anything was done on these lines similar arrangements would have to be made for ascertaining the special requirements of other parts of the overseas Dominions, such as India, Australia, and South Africa. The delegates from the societies brought forward certain proposals concerning the method of revision, and many suggestions on the subject were offered. At the conclusion of the conference the President stated that these proposals and suggestions would be carefully considered by the Pharmacopœia Committee at a meeting which would take place about the middle of March, after which he would ask the delegates to meet the Pharmacopœia Committee again.

ROYAL INSTITUTION.—On Friday, March 12th, Sir J. J. Thomson will lecture at 9 P.M. on Radiation from Electric Discharges.

IT is reported that Dr. R. Gordon Craig, of Sydney, has given £20,000 to found a Fellowship in Urology in the University of Sydney.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society will be held at the Miller General Hospital, Greenwich, S.E., on Friday, March 12th, at 8.15 P.M., when Mr. C. A. Joll will read a paper on Modern Gastric Surgery.

ROYAL SOCIETY OF ARTS.—Amongst forthcoming lectures are three on Thermometry by Mr. W. F. Higgins, M.Sc., at 8 P.M., on March 15th, 22nd, and 29th, and one on Women and Children in Indian Industry, by Lady Chatterjee, D.Sc., on March 19th, at 4 P.M.

ROYAL SANITARY INSTITUTE.—A sessional meeting is to be held at the Town Hall, Hastings, on March 12th and 13th. On Friday, at 8 P.M., Prof. H. R. Kenwood will give a semi-popular lecture called a City of Health. On Saturday, at 10.30 A.M., a discussion on Mothercraft and Fathercraft will be opened by Dr. G. R. Bruce, Miss Hester Viney, and Dr. J. Fenton. School clinics, welfare centres, and other places of interest will be visited.

EPSOM COLLEGE.—The Council of Epsom College will shortly award a St. Anne's Home Scholarship of the value of £18 a year. Candidates must be between the ages of 7 and 12, and must be the orphan daughters of duly qualified medical men who have been for not less than five years in independent practice in England or Wales. Particulars can be obtained from the Secretary, at the office of the College, 49, Bedford-square, W.C. 1.

AMONG the works announced for publication this spring by Messrs. Martin, Hopkinson and Co., Ltd., is a book called "Medical Aspects of Birth Control," which contains contributions from Dr. R. C. Buist, Dr. Letitia Fairfield, Dr. Arthur Giles, Prof. Leonard Hill, F.R.S., Dr. Crichton-Miller, Sir Arthur Newsholme, Sir John Robertson, and Dr. Mary Scharlieb, and is edited by the Rev. Sir James Marchant.

UNIVERSITY OF BASLE: LECTURES BY PROF. BRAMWELL.—At the invitation of the University authorities Prof. Edwin Bramwell, of Edinburgh, gave a series of lectures before teachers and students between Feb. 15th and 27th. Selected Chapters of Neurology was his subject, and the lectures were greatly appreciated. Prof. Staehelin, of the Basle Medical Faculty, in a vote of thanks to Prof. Bramwell, remarked that science is international and that every worker has access to the scientific literature of other countries. But the scientists of different nations have different ways of approaching and solving their problems, and nothing is more interesting and fruitful than to observe scientific workers of other countries handling the problems of their own sphere. Prof. Bramwell impressed his audience with the feeling that much can be learnt and gained from the English outlook in clinical medicine.

"BRENTHOL H" AND A DYE-WORKER'S DEATH.—An adjourned inquiry into the cause of the death of James Lee (41), Rochdale, who was employed at a kid-glove dye-works, Middleton, was held on Feb. 24th by the coroner, Mr. W. W. Surridge, at the Manchester City Coroner's Court. The firm at which Lee worked used a substance known as "Brenthol H," and it was suggested that fumes arising from the mixture of this substance with soda used in the process of dyeing had affected Lee, who died at the Manchester Royal Infirmary on Feb. 7th. The post-mortem showed that death was due to toxic jaundice. No such case has hitherto been recorded. The coroner said that as there was not sufficient evidence to show what were the prevailing conditions which led to the man's death he would return an open verdict.

AMALGAMATION OF THE DUBLIN HOSPITALS.—At the annual meeting of the Incorporated Orthopædic Hospital of Ireland, Mr. R. C. B. Maunsell, President of the Royal College of Surgeons in Ireland, stated that the scheme for the amalgamation of at least five of the Dublin hospitals was in abeyance in consequence of difficulties created by the question of the Medical Register in the Free State. The Rockefeller Foundation was about to grant a large sum when this question arose and the negotiations were broken off pending a settlement. The five hospitals concerned—Sir Patrick Dun's, the Adelaide, Mercers', the Meath, and the City of Dublin—have agreed in principle to amalgamation and the erection of a new hospital of 750 beds at a cost of about £750,000. This would be 100 beds more than the present aggregate, and it is estimated that the existing institutions could be sold for £350,000.

The Hôpital des Enfants Malades, 149, rue de Sèvres, Paris, is to hold a special vacation course from April 7th to 17th on the Diseases of Children

**Hawick Cottage Hospital.**—Lady Violet Astor has dedicated an additional wing which she has provided as a memorial to her brother, the Hon. G. W. E. Elliot, who was killed in action in 1917. The new wing, which will be used for orthopædic and electrical work, includes two private wards.

**Printers' Convalescent Home.**—Lord Riddell on Feb. 20th opened the Hermitage Convalescent Home for the Printers' Medical Aid and Sanatoria Association at Hastings. The Association has been very active since 1909, and the income has grown beyond all optimistic expectation. For the extensive benefits offered the members pay only a penny a week. Last year there were 112 convalescent home cases and 70 sanatoria cases.

**The Site of Bethlem Hospital.**—Subject to Parliamentary sanction, Lord Rothermere has purchased the site of Bethlem Hospital in Southwark for £155,000. The area of between 14 and 15 acres is to be converted into a playground and park to be known as the "Geraldine Mary Harmsworth Park" as a memorial of the late Mrs. Harmsworth, the mother of Lord Rothermere and the late Lord Northcliffe.

**The late Dr. E. S. Tresidder.**—The death of Dr. Edward Stanley Tresidder took place on Feb. 23rd at his residence at Askern, near Doncaster, in his sixty-seventh year. A student at Guy's Hospital, London, he qualified M.R.C.S. Eng. in 1882 and L.R.C.P. Lond. a year later. He had been in practice at Askern for about 12 years and had been divisional surgeon of the Askern Nursing Home since its inception in 1917. In recognition of an active interest in ambulance work stretching over more than 35 years, he was made an honorary associate of the Order of St. John of Jerusalem about two years ago. Dr. Tresidder was the second son of the late Surgeon-General J. N. Tresidder, I.M.S.

**Brighton, Hove, and Preston Dispensary.**—With reference to the Hove branch, which is known as the Hove Hospital, it was stated at the annual meeting held recently that Mr. Bernhard Baron had given £2500 to defray the cost of a new wing, in memory of his wife. This probably meant an addition of ten beds, and the cost of running the hospital would be increased from £1000 a year to £5500 a year. Hove, with its population of 46,000, only subscribed £825 annually. For the institution as a whole the ordinary expenditure was in excess of the ordinary income by £804. Large increases of all classes of patients were recorded during the year.

**Sussex Maternity and Women's Hospital.**—This institution at Brighton is flourishing. Only a few years ago it removed from its old inadequate premises, and now, despite the opening of an additional ward, still further room is wanted. During 1925 238 women were treated as in-patients, 385 mothers received attention at childbirth, 3686 out-patients attended, 1796 examinations were made in the antenatal clinic, 1080 homes were visited by the nurses, 73 patients were accommodated in the separate wards for private maternity patients, and 55 were admitted into other wards at the Hove branch. The accounts show a strong financial position; the excess of income over expenditure in 1925 was £2190.

**International Society of Medical Hydrology.** This year this society is to hold its annual meeting in Czecho-Slovakia from April 16th to 20th. A varied programme has been arranged, including visits to Karlsbad, Marienbad, Franzensbad, Pistyan, and the health resorts of the Tatra mountains. There will be papers and discussions, amongst others, on the following subjects: Endocrine Deficiency and Spa Treatment, Dr. M. Porges (Marienbad); the Treatment of Disorders of the Liver by Waters and Baths, Dr. Kraus and Dr. H. Simon (Karlsbad); the Balneological Treatment of High Blood Pressure, Dr. Pflanz (Marienbad); the Treatment of Chronic Rheumatic Affections by Mud Baths, Dr. L. Schmidt (Pistyan), Prof. A. Vinaj (Andorno), Prof. E. Astori (Abano), and Dr. E. Tommasi (Agnano); the Care of Medicinal Springs, Dr. Zörkendörfer (Franzensbad). The medical faculties of the Universities of Prague have arranged to receive the society, and the Czecho-Slovakian and other continental railways have offered concessions. Members of the medical profession other than members of the International Society will be made cordially welcome if they wish to join this study-tour to Czecho-Slovakia. Full particulars of the journey, programme, and facilities may be had from the hon. secretary, Dr. E. P. Poulton, at 36, Devonshire-place, London, W. 1.

**Manchester Royal Infirmary.**—The post-graduate lectures at the Royal Infirmary for the second half of the year 1925–26 began on Tuesday, March 2nd, at 1.15 P.M., when Dr. F. Craven Moore lectured on the Diagnosis of Nephritis. From then until May 21st (except at Easter) there will be lectures by members of the Royal Infirmary staff on Tuesdays and demonstrations of clinical cases and of medical methods on Fridays.

**Manchester University's Shrove Tuesday "Rag."** As a result of the University's Shrove Tuesday "rag" the Manchester and Salford Hospitals will receive this year about £11,000. The sums collected in previous years were £656 in 1922, £1033 in 1923, £2856 in 1924, £6023 in 1925. This year's collection exceeds the sum raised by the University of Glasgow, which was £10,560. The street collecting boxes yielded £6004, and the publication "Rag Rag" with its advertisements and sales realised £3700.

**Manchester Northern Hospital for Women and Children.**—At the annual meeting it was stated that the number of in-patients during last year was 220 in excess of the previous year and also that the hospital was not in debt. The hospital is situated in the midst of an ever-growing and populous neighbourhood, and its present accommodation has become quite inadequate. It has been resolved to erect a new hospital at a cost of £150,000. A site covering 10,655 square yards has been given by the President, Sir Edward Holt, and plans for the new hospital have been prepared. There are now in the hospital 22 beds for women and 50 cots for children, and in the new building it is proposed to have 220 beds. Last year 1218 persons were treated in the wards and 4278 in the dispensary. Towards the £150,000 required the committee has accumulated over £35,000, and the general public will be appealed to for the remainder. Amongst the subscriptions received are £5000 from Sir Edward Holt, Bleachers' Association £2000, R. S. Bodington £1000, Groves and Whitnall Ltd. £1000, Lady Holt £1000, and W. Morton Philips £1000. Over £16,000 has been allocated from the general funds of the hospital.

**The late Dr. J. Derham-Reid.**—Dr. James Derham-Reid, who died of pneumonia on Feb. 17th at the age of 17, had lived in Bolton nearly all his life and is said to have had one of the largest practices in Lancashire. He studied medicine at the Manchester Medical School and at the Middlesex Hospital, London, and after qualifying as M.R.C.S., L.R.C.P. in 1905, he practised for a time in Walkden. Then he moved to the Daubhill district of Bolton, where he became very popular. The affectionate esteem in which he was held by those who live in the district was shown in a remarkable and spontaneous manner at his funeral on Feb. 23rd. Representatives of all sides of the life of the neighbourhood began to assemble at the church an hour before the service began, and the blinds in the shops and houses in the neighbourhood were drawn. Dr. Derham-Reid joined the R.A.M.C. (Territorial Force) in 1915, was promoted to the rank of major, and won the Military Cross. He leaves a widow and six young children.

**Glasgow Royal Cancer Hospital.**—In the new X ray department elaborate precautions have been taken to counter the penetrative power of the Erlangen rays, and the walls of the X ray rooms have an ample coating of lead, which is not only the cheapest metal, but that which offers the greatest resistance to the penetrative rays. In the operator's room 17 lb. of lead per square foot are used as a lining from floor to ceiling, and in order that a patient may be kept under constant observation, windows of specially prepared glass of a high degree of protective power have been inserted. Sir G. T. Beatson, who has been surgeon to the hospital for over 30 years, has written an interesting pamphlet descriptive of the building.

**The late Dr. J. A. Sutherland.**—The interment of Dr. John Alexander Sutherland took place at Cleckheaton Old Cemetery on Feb. 21st. Many medical colleagues were present and various institutions with which he was connected were represented, including the North Bierley Joint Hospital, of which he had been medical superintendent ever since its foundation, and the St. John Ambulance and Nursing Division Corps from Spen Valley. Graduating in medicine at the University of Edinburgh in 1878, Dr. Sutherland served as assistant surgeon in the Leith Hospital, and as house physician at the Royal Infirmary, Edinburgh. Besides being physician to the North Bierley Joint Hospital he was also medical officer of health for Cleckheaton. At the time of his death he was in his seventieth year. Dr. Sutherland has been described as "a typical Scotsman, who, despite his long residence in the West Riding, never entirely lost the accent of his native land." Well known to all in the Spen Valley, he was affectionately called "the old doctor," and his death will leave a big gap in the intimate life of the district.

**PEMPHIGUS NEONATORUM.**—The Ministry of Health has approved the resolution of the Manchester City Council ordering that pemphigus neonatorum be classed as a notifiable infectious disease from March 10th to June 30th of this year.

**ST. THOMAS'S HOSPITAL.**—Three popular lectures on physics are to be given at the hospital on March 9th, 23rd, and 30th, at 5 P.M. The first, on the Nature of Human Speech, will be given by Sir Richard Paget. Four lectures on the Importance of Vitamins are to be given on March 11th, 12th, 15th, and 16th, at 5 P.M., by Prof. R. H. A. Plimmer.

**DONATIONS AND BEQUESTS.**—Mr. Alfred Shuttleworth, of Eastgate House, Lincoln, left large bequests to servants and dependants, and £1000 to the Lincoln County Hospital, and £1000 to the Lincoln General Dispensary.—Major David Milne, Dundee, left £1000 each to the Royal Victoria Hospital, Dundee, and the Dundee Royal Infirmary, and £500 to the Dundee Sick Poor Nursing Society.

**MIDDLESEX HOSPITAL.**—A scientific exhibition and demonstration in the research departments of the hospital and medical school is to be held on Wednesday, March 10th, from 9 P.M. to 11.30. From that time until March 16th the exhibition of ultra-violet radiation apparatus and other electro-therapeutic apparatus in the evacuated wards of the hospital will remain open between 11 A.M. and 6 P.M. daily. Admission will be free, on presentation of a visiting card, to members of the profession and others directly interested.

**CONFERENCE ON TUBERCULOSIS.**—The Tuberculosis Society and the Society of Superintendents of Tuberculosis Institutions are to hold a joint meeting at Cambridge from March 25th to 27th. Amongst those who will give addresses are Dr. James Crockett, Dr. G. Marshall, Sir Humphry Rolleston, Sir StClair Thomson, Prof. Edgar Collis, Prof. Lyle Cummins, and Dr. H. de Carle Woodcock. A limited number of rooms is available at St. Catherine's College. Information may be had from Dr. F. J. Blackmore, Tuberculosis Dispensary, Maxey-road, Plumstead, S.E. 18.

**VENEREAL DISEASE AND THE MERCHANT SERVICE.**—The British Social Hygiene Council held a conference on Feb. 25th on the welfare of the mercantile marine in the Port of London, with special reference to the provision of facilities for recreation. Mr. Greaves-Lord, K.C., M.P., took the chair, and many philanthropic societies were represented. The Chairman said that venereal disease amongst seamen was a difficult problem. They were long from home and found special temptations to vice on their return, and counter-attractions were inadequate. Miss Agnes Weston had shown what missions could do, but not every seaman was amenable to them. Mr. Cuthbert Laws said that seamen should not be treated as children; they were just as sophisticated nowadays as other working men. Mr. Leonard Bowden, speaking for Mr. Havelock Wilson, of the Seamen's and Firemen's Union, said that excellent work had been done for many years by the union. It was necessary to get rid of the idea that a cup of coffee in a draughty, white-washed room was a sailor's idea of a good time in port. There ought to be a club on every ship, and recreation grounds should be available at all times for men coming ashore. Mr. E. B. Turner said that what the sailor needed specially was recreation. Organised recreation was mainly responsible for a reduction of the figures for venereal disease amongst troops at Aldershot from 327 per 1000 in 1885 to 30 in 1913. Athletic clubs should welcome seamen as visitors or spectators; a love of sport must be implanted. Fleet-Surgeon W. E. Home said that there were two sides to the question; lack of self-control amongst civilians must not be forgotten. If sailors could not talk to good women in port they would talk to a bad one. In the U.S.A. a scheme had been started in which attractive and able women of character set themselves to organise entertainment. Admiral Tupper said that young men should go on board ships in port and persuade the sailors to come ashore and play games. Mr. Ganley advocated sexual education in elementary schools. Mr. Barker pointed out that existing societies were doing good work, which was only limited by lack of funds. Mrs. Neville Rolfe, secretary of the British Social Hygiene Council, made three propositions—that municipal authorities should provide recreation facilities for sailors coming into port; that retired seafaring men should coördinate such facilities in their ports and encourage seamen to use them; and that decent citizens should open their homes to men on whom their prosperity often depended. A resolution was adopted advocating coöperation by the various organisations concerned.

# Medical Diary.

## SOCIETIES.

THE ROYAL SOCIETY, Burlington House, Piccadilly, W.

THURSDAY, March 11th.—4.30 P.M. *The following papers will be read:* J. A. Campbell: The Effects of Ultra-Violet Radiation upon the Metabolism of Healthy Subjects. (Communicated by Dr. Leonard Hill.). E. Ponder: A Study of Certain Forms of Inhibition and Acceleration of Hæmolysis. (Communicated by Sir E. Sharpey Schafer.) S. B. Schryver and H. W. Buston: The Isolation of Some Undescribed Products of Hydrolysis of Proteins. (Communicated by Sir John Farmer.) *Papers to be read in title only:* A. W. Greenwood and F. A. E. Crew: Studies on the Relation of Gonadic Structure to Plumage Characterisation in the Domestic Fowl. (Communicated by Prof. R. C. Punnett.) E. P. Cathcart and W. A. Burnett: The Influence of Muscle Work on Metabolism in Varying Conditions of Diet. E. Fischer: The Heat Liberated by the Beating Heart. (Communicated by Prof. A. V. Hill.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, March 8th.—5 P.M., WAR, at the Royal Army Medical College, Grosvenor-road, S.W. Demonstrations on Recent Work on Problems of Hygiene by Surgeon-Commander T. B. Shaw, R.N., and officers of the Hygiene Department, Royal Army Medical College.

TUESDAY.—5.30 P.M., SURGERY, MEDICINE, ELECTRO-THERAPEUTICS, and THERAPEUTICS. Discussion: The Treatment of Exophthalmic Goitre (contd.). 8.30 P.M., PSYCHIATRY. Dr. Thomas Beaton: The Clinical Relationship between Psychological Disorders.

WEDNESDAY.—5.30 P.M., SURGERY, MEDICINE, ELECTRO-THERAPEUTICS, and THERAPEUTICS. The Treatment of Exophthalmic Goitre (conclusion).

THURSDAY.—5.30 P.M., TROPICAL DISEASES AND PARASITOLOGY. Dr. J. Gordon Thomson: Pseudo Parasites of Man. Mr. J. Ramsbottom: The Classification of Pathogenic Fungi. 8 P.M., NEUROLOGY, at the National Hospital for the Paralysed and Epileptic, Queen square, W.C.

FRIDAY.—5.30 P.M. (Cases at 5 P.M.). CLINICAL. Dr. Dorothy Hare: Rheumatoid Arthritis with Multiple Fibrous Nodules. Dr. L. S. T. Burrell: Charcot's Joint. Dr. Bernard Myers and Mr. Rodney Maingot: Splenectomy for Three Cases of Essential Thrombocytopenic Purpura Hæmorrhagica. Dr. Saxby Willis: Sarcoma of Thorax. Dr. Chandler: Diabetes in a Child associated with Pancreatic Cyst. 5 P.M., OPHTHALMOLOGY. Clinical Meeting at the Royal London Ophthalmic Hospital, City-road (Moorfields), E.C.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, March 8th.—8.30 P.M., Discussion on Obscure Pyrexia in Adults, to be introduced by Sir Thomas Horder, Bart., and Dr. C. E. Lakin.

BIOCHEMICAL SOCIETY.

SATURDAY, March 13th.—2.15 P.M. (In the Biochemical Department, University College, Gower-street, W.C.). C. R. Harington: Chemistry of Thyroxin: (*a*) Method of Isolation from the Thyroid Gland. (*b*) Constitution and Synthesis of Iodine-free Thyroxin. H. J. Channon: Some Experiments on the Biological Significance of Squalene (Spinacene). H. J. Channon and G. F. Marrian: An Unidentified, Unsaturated Hydrocarbon Occurring in Mammalian Liver. I. M. Heilbron: The Chemical Nature of Squalene (Spinacene). F. H. Carr and E. A. Price: Colour Reactions Attributed to Vitamin A. H. Jephcott and A. L. Bacharach: Studies in the Vitamins of Cod-Liver Oil, Part I. H. S. Raper: The Production of 3:4 Dihydroxyphenylalanine from Tyrosine by the Action of Tyrosinase. R. K. Cannan, P. Haas, and T. G. Hill: Oxidation-Reduction Potential of Hermidin (Chromogen of Mercurialis perennis). C. Dorée and E. C. Barton-Wright: A Note on the Stone-Cells of the Pear. Margaret H. O'Dwyer: On the Nature of the Hemicelluloses. H. D. Carey: The Relation Between Hydrogen Sulphide, Hyposulphites, and Thiosulphates; by a New Method of Structural Formulæ. E. Ponder: The Shape of the Erythrocyte and its Respiratory Function.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, March 9th.—5 P.M., Prof. W. W. C. Topley: Experimental Epidemiology (last Milroy Lecture).

THURSDAY.—5 P.M., Dr. Bernard Hart: Development of Psychopathology, and its Place in Medicine (first Goulstonian Lecture).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

FRIDAY, March 12th.—5 P.M., Sir Arthur Keith: Demonstration on Parts concerned in the Secretion and Absorption of Cerebro-spinal Fluid.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

WEDNESDAY, March 10th.—Dr. Harrison: Blood Analysis and Discussion of Selected Laboratory Reports.

THURSDAY.—4 P.M., Mr. A. T. Pitts: Care of the Mouth.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole street, W.

MONDAY, March 8th, to SATURDAY, March 13th.—Fellowship of Medicine lecture, at the Medical Society, 11, Chandos-street, W. Thursday, at 5 P.M., Colonel F. E. Fremantle, M.P., on the Economics of Public Health. Free to all members of the medical profession. Special afternoon demonstration in Clinical Surgery on Thursday, at 5 P.M., at St. Mark's Hospital, by Mr. E. T. C. Milligan. —CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Post-graduate course in Gynæcology. Operations, lectures, and demonstrations daily.—ROYAL EYE HOSPITAL, St. George's Circus, Southwark, S.E. A series of demonstrations on the Diagnosis and Treatment of Diseases of the Eye. Monday to Friday, every afternoon at 3 P.M. Further information from the Secretary of the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, March 8th.—10 A.M., Surgical Out-patients: Mr. W. E. Tanner. 10.30 A.M., Gynæcological Operations: Mr. A. E. Giles: Throat, Nose and Ear Operations: Mr. W. Ibbotson. 2 P.M., Medical, Surgical, and Gynæcological Clinics, Operations. 6.30 P.M., Venereal Department.

TUESDAY.—2 P.M., Medical, Surgical, Throat, Nose and Ear Clinics, Operations. 4.30 P.M., Mr. W. Ibbotson: Treatment of Chronic Rhinitis.

WEDNESDAY.—10.30 A.M., Surgical Operations: Mr. E. Gillespie. 2 P.M., Medical, Eye, and Skin Clinics, Operations. 5.30 P.M., Venereal Department.

THURSDAY.—10.30 A.M., Dental Out-patients: Mr. E. S. Pierrepont. 2 P.M., Medical, Surgical, and Throat, Nose and Ear Clinics, Operations. 5 P.M., Operations.

FRIDAY.—10.30 A.M., Eye Operations: Mr. N. Fleming, 2 P.M., Surgical, Medical, and Children Clinics, Operations. 3 P.M., Gynæcological Clinic. 6.30 P.M., Venereal Department.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: FEBRUARY-MARCH, 1936.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, March 8th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., The Neuro-Muscular System, III., The Voluntary Motor System: Dr. Kinnier Wilson.

TUESDAY, March 9th.—2 P.M., Out patient Clinic: Dr. Walshe. 3 30 P.M., Compression Paraplegia: Dr. Hinds Howell.

THURSDAY, March 11th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Epilepsy: Dr. Martin.

FRIDAY, March 12th.—2 P.M., Out patient Clinic: Dr. Adie. 3.30 P.M., The Neurono-fixative Poisons, Tetanus, Rabies, Diphtheria: Dr. Collier.

The fee for the Course, including Pathology lectures, is £5 5s. For those who hold Perpetual Tickets the fee is £3 3s.

Mr. Armour and Mr Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. GREENFIELD, Dean of Medical School.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester square, W.C.

TUESDAY, March 9th.—5 P.M., Dr. Wilfrid Fox: Nævi.

THURSDAY.—5 P.M., Dr. H. G. Adamson. Benign Growths of the Skin.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Grays' Inn road, W.C.

FRIDAY, March 12th —4 P.M., Dr. Andrew Wylie: Growths of the Larynx.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

FRIDAY, March 12th.—3.30 P M. (at the Royal Infirmary), Mr. Finch. The "Chronic" Abdomen.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

TUESDAY, March 9th.—4.15 P.M., Dr. W. B. Anderton: Criminal Abortion.

FRIDAY.—4 15 P.M, Dr A. Ramsbottom: Demonstration of Medical Cases.

## Appointments.

GIBSON, JOHN M., M.D., D P.H. Belf., has been appointed Medical Officer of Health and School Medical Officer for the Borough of Hyde.

North Middlesex Hospital: BROWN, L G., M.D. Oxf., F.R.C.S. Eng, Oral Surgeon, DE CARY, F. P., L.R.C.P. Lond., M.R.C.S., FRANCIS, C. P., M B., B.S. Lond., Anæsthetists.

Certifying Surgeons under the Factory and Workshop Acts: THISTLETHWAITE, W., M B., Ch.B. Leeds (Sherburn); GLEN, C., M.B, Ch.B. Glasg (Cumbernauld, Dumbarton).

## Vacancies.

*For further information refer to the advertisement columns.*

*Birmingham, Queen's Hospital.*—H.P., H S.'s, Cas. H.S, and Res. Anæsthetists. Each £70. Also Pathologist. £100.

*Bolingbroke Hospital, Wandsworth Common, S.W.*—Res. M.O. £200.

*Bradford, Grassington Sanatorium.*—Med. Supt. £100.

*Brighton, New Sussex Hospital, Windlesham road.*—H.S. At rate of £50.

*Capetown City.*—Asst. M.O. £800.

*Cardiff City Mental Hospital, Whitchurch, near Cardiff.*—Res. Clin. Asst. for six months. 50 guineas.

*Cardiganshire County Council, Aberystwyth.*—M.O.H. £800.

*Carlisle, Cumberland Infirmary.*—Jun. H.S. At rate of £135.

*Central London Ophthalmic Hospital, Judd-street, W.C.*—Asst. S.

*Charing Cross Hospital.*—Surg. Reg., Med. Reg. Each £150. Also Obstet. Reg.

*Chester Royal Infirmary.*—Asst. H.S. £125.

*Croydon Mental Hospital, Upper Warlingham, Surrey.*—Asst. M.O. £350.

*Dreadnought Hospital, Greenwich, S.E.*—H.S. and H.P. Each at rate of £110.

*Folkestone, Royal Victoria Hospital.*—Res. M.O. At rate of £150.

*Freemasons Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.*—Res. M.O. At rate of £250.

*Hampstead Borough.*—Four Consulting Obstetricians.

*Hospital for Epilepsy and Paralysis, Maida Vale, W.*—Hon. S. to Ear, Nose, and Throat Dept.

*Hospital for Women, Soho-square, W.*—Res. M.O. At rate of £100.

*Hull City and County of Kingston-upon-Hull Maternity and Child Welfare Dept.*—Asst. M.O. £600.

*Hull Royal Infirmary.*—Asst. H.S. £150.

*Hull, Victoria Hospital for Sick Children, Park-street.*—Res. H.P. £80.

*Lancashire County Mental Hospital, Rainhill.*—Fifth and Sixth Asst. M.O.'s. £350.

*Liverpool Eye and Ear Infirmary, Myrtle-street.*—Hon. Asst. S.

*Liverpool Port Sanitary Authority.*—Asst. Port M.O. £700.

*London Hospital, E.*—Gynæcological Reg. £400. Also Cardiographic Dept., Paterson Research Scholar. £400.

*London Lock Hospital, 283, Harrow-road, W.*—Second H.S. £150.

*Manchester, St. Mary's Hospitals.*—Three H.S.'s. Each at rate of £50.

*Middlesex Hospital, W.*—Reg. to Ear, Nose, and Throat Dept. £300.

*National Hospital for the Paralysed and Epileptic, Queen-square, W.C.*—Med. Reg. £200. Also Orthopædic S.

*Newcastle-upon-Tyne, Hospital for Sick Children.*—Sen. and Jun. Res. M.O.'s. At rate of £120 and £100 respectively.

*Northampton General Hospital.*—Hon. Asst. S.

*Northumberland County Council, Wooley Sanatorium, near Hexham.*—Asst. Med. Supt., &c. £600.

*Plymouth, Homœopathic and General Hospital.*—H.S. £150.

*Queen's Hospital for Children, Hackney-road, Bethnal Green, E.*—Res. M.O. £200. H.P. At rate of £100.

*Royal Free Hospital and Lond. Sch. of Medicine for Women, Gray's Inn-road, W.C.*—Sen. Asst. Path. Full time. £600.

*Royal Northern Hospital, Holloway, N.*—H.S. and Obstet. H.S. Each at rate of £70. M.O. to Out-patients. At rate of £125.

*St. Bartholomew's Hospital.*—Chief Assts. in Ophth. Depts.

*St. John's Hospital, Lewisham, S.E.*—Res. H S. At rate of £100.

*St. Luke's Hospital, Cale-street, Chelsea, S.W.*—First Asst. M.O. £120.

*St. Mary's Hospital, Institute of Pathology and Research.*—Research Studentship. At rate of £200.

*St. Paul's Hospital for Skin and Genito-Urinary Diseases, Endell-street, Holborn, W.C.*—H.S. £200.

*Salisbury General Infirmary.*—H.S. £150.

*Stockton-on-Tees, Stockton and Thornaby Hospital.*—Sen. H.S. £250.

*Sunderland Royal Infirmary.*—H.S. £140.

*Tottenham Maternity and Child Welfare Committee.*—Asst. M.O. at the Ante- and Post-natal Clinics.

*Wallsall General Hospital.*—Sen. H.S. and Jun. H.S. At rate of £175 and £125 respectively.

*Weir Hospital, Grove-road, Balham, S.W.*—Jun. Res. M.O. £100.

*West London Hospital, Hammersmith, W.*—H.P. and two H.S.'s. Each at rate of £100.

*Windsor, King Edward VII. Hospital*—Hon. Asst. S.

*York County Hospital.*—H.P. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacancies for Certifying Factory Surgeons at Fordingbridge (Hants), Conway (Carnarvon), and at Bradford, South (Yorks, W. Riding).

## Births, Marriages, and Deaths.

### BIRTHS.

CHURCHER.—On Feb. 24th, the wife of D. G. Churcher, F.R.C.S., Tarporley, Cheshire, of a son.

### MARRIAGES.

BURKE—BLACKWOOD.—At St. Cuthbert's Parish Church, Edinburgh, on Feb. 18th, by the Rev. J. Donald Beattie, B.A., Myles Edmund Towers Burke, L.R.C.P. & S. Edin., and L.R.F.P. & S. Glasgow, Finchley, London, to Margaret M'Arthur Blackwood, Logan Cottage, Dunbar.

KNAGGS—SMITH.—At St. George's Church, Bickley, by the Rev. Canon Baggallay, Robert Lawford Knaggs M.C.Cantab. F.R.C S., to Adrienne Ernestine Blanche (née Blouet-Dargonne), widow of Morton William Smith, Recorder of Rochester.

### DEATHS.

TRESIDDER.—On Feb. 23rd, at Askern, Edward Stanley Tresidder, M.R.C.S. Eng., L.R.C.P. Lond., in his 67th year.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Comments, and Abstracts.

## THE DIARY OF A PARAPLEGIC PATIENT

BY E. GOWLLAND, D.S.O., M.B. LOND.,
LIEUT.-COLONEL, T.D., COMMANDANT, STAR AND GARTER HOME FOR DISABLED SAILORS AND SOLDIERS, RICHMOND, SURREY

THIS is an attempt to give some idea of the normal daily routine of many of the patients in the Star and Garter Home for Disabled Sailors and Soldiers, suffering from the effects of wounds and injuries of spine and resulting paraplegia, which will indicate the meticulous care which is essential in order to avoid deformities and the occurrence of bedsores with subsequent infection of bladder, kidneys, &c., and will emphasise the necessity for constant attendance by skilled nurses and orderlies in this class of work.

The routine starts at 5.30 A.M., when a cup of tea is brought to the patient by a night orderly. At 6 A.M. he is either washed or a bowl of water is brought to him. This process being finished he turns to his morning paper, which he peruses until 8 A.M., when breakfast is served, tea or coffee being placed on a locker within easy reach. Breakfast finished, the day's treatment commences. Where the paralysis is complete in the lower half of the body an enema is administered two or three times a week, as these men are incontinent, and it is only by frequently clearing the lower bowel that they are enabled to get up and pursue any avocation without danger to themselves and considerable unpleasantness. The enema has not the same effect as on an ordinary individual. The bowel empties itself very gradually and necessitates constant attention, the draw sheet having to be frequently changed to avoid soaking in fæcal matter, which might precipitate the much-dreaded danger of bedsores or trophic ulcers. It must be realised that after removal of the bed pan there usually occurs a prolonged "leaking." After this process, which takes from one to one and a half hours, the bladder is washed out, and should the patient have a suprapubic opening, the suprapubic tube is changed, and a fresh sterilised tube is inserted and strapped to the abdominal wall. This takes about 20 minutes. Then, two or three times a week he is bathed (unless he is a suprapubic case). This means that the patient has to be lifted from his bed to his ward chair and wheeled by an orderly to the bathroom, where pyjamas or night clothes are removed from him, and he is lifted into the bath and washed by an orderly. He must then be lifted from the bath, usually by two orderlies, and placed in a blanket which has been spread over his ward chair. He is thoroughly dried, quickly wheeled back, and lifted into his bed, his pyjamas then being replaced. On the days when he is not bathed he may be given a radiant heat bath, diathermy, or such other treatment as may be ordered for the relief of painful spasm of legs, &c. On his return to bed the nursing sister arrives with a dressing trolley. His back is thoroughly rubbed with methylated spirit, any trophic ulcers are cleaned and dressed, careful attention being given to all bony prominences at the lower part of the back and hips, which are then padded with Gamgee tissue, this being secured by a many-tailed bandage. Attention is then given to the knees, heels and ankles, which are rubbed (using firm, circular movements) with methylated spirit. The heels are protected from pressure on the bed by placing a small cushion under the Achilles tendons. The feet are propped up by a firm bolster, and small cushions are placed under the knee-joints to prevent hyperextension. The toes and knees are protected from the weight of bedclothes by the constant use of a cradle. When this process is finished he is ready for his massage, and it is found that 20 to 30 minutes massage of legs, back, and abdomen, together with passive movements, is essential for the well being of these cases.

The patient now rests until about 11.30, when an orderly proceeds to dress him on his bed; his rubber urinal is fixed, and he is again lifted into his ward chair. This process takes some 20 minutes. The method of adjusting a paraplegic into a ward chair is not so simple as it may sound—air cushions and other cushions have to be carefully arranged to suit individual requirements, the patient's legs have to be carefully placed on the foot board, and in many cases strapped down, as so many of these men suffer from severe spasmodic contractions. Our paraplegic now proceeds to a lift, which takes him down to the dining hall, where specially designed furniture enables him to sit comfortably up to the table. After dinner many of the men who are interested in handicrafts go to the various workshops—engineering, carpentry, spinning, leather work, basket work, boot repairing, photography—for all of which occupations facilities are provided in this home. Three of our men also edit and run a quarterly magazine for the home. Others go to the common room, where they, perhaps, play cards or other games, or to the billiards room, where they play from their chairs, and many of these men play quite a good game, frequently making breaks of 20 and over. It is extremely difficult to play from one of these wheeled chairs, even for a man who is normally a good player.

It will thus be seen that their life is comparatively strenuous, considering that most of them are completely paralysed "below the belt." They have tea about 3.30, after which, on two or three days a week there is some afternoon entertainment either in the common room or cinema hall. Supper at 7 P.M., after which a large number go back to their beds, again being lifted from chair to bed and undressed by an orderly. Subsequently, toilet of the back is again carried out by a nursing sister. Medicines, such as aperients, are given at about 9 P.M., when lights are lowered and the night sister and orderly take over the patient. His rubber day urinal is changed for the "swan neck" bottle urinal, and after perhaps listening for an hour to a wireless concert he goes to sleep. The nights, however, are by no means undisturbed. About 1 A.M. the urine bottle is emptied, cleansed and replaced, and it not infrequently happens that he wakes to find that his bowels have acted and he is lying in excrement, in which case an orderly is summoned, who washes and cleanses the patient and changes his draw-sheet. The urine bottle must always be carefully watched by orderlies; any overflow means the soaking of the patient and again cleansing and changing of draw sheet.

It must be realised that most of these patients have lost both sensation and power of movement, so that it is essential that nursing sisters and orderlies shall be ever on the alert to prevent excretory mishaps, not that these mean immediate discomfort to the patient (it would be better if they did!) but because of the danger: (1) of the occurrence of bedsores, and (2) of the infection of existing trophic ulcers, which dangers must always be borne in mind by those legislating for the adequate treatment of the paraplegic.

It must be remembered that in these cases: (1) the circulation in the skin is deficient; (2) the skin is very apt to break down under quite minor irritations; (3) the infection of an existing trophic ulcer, or the occurrence of a new bedsore is fraught with danger to the patient, by reason of the fact that any septic infection in such cases is very liable to be followed by a general infection, cystitis, or pyelitis—and pyelitis is almost always the "end condition" in the paraplegic.

These patients nearly always spend one or two days per week entirely in bed—usually their "enema days." Most of them go out in hand propelled tricycles, with or without a motor attachment; they must be lifted into these vehicles from their ward chairs and carefully arranged therein, with air cushions, pillows, &c., and, of course, lifted back on their return. The terms "trophic ulcer" and "bedsore" have been used—these terms may appear synonymous. In this paper, however, the differentiation is meant to indicate that a trophic ulcer is an inevitable occurrence and cannot be healed (but it can be kept surgically clean); whereas a bedsore is an accident and can normally be healed. In this sense a "bedsore" is usually an indication that details of nursing technique have not been thoroughly carried out, and it is interesting to note that many patients, on return from leave, exhibit bedsores.

It will be gathered that the working day of the paraplegic patient and of those who are privileged to look after him is indeed a strenuous one, and it is only by cheerful coöperation on the part of the one, together with assiduous attention to the rules of surgical cleanliness and good nursing on the part of the others, that these cases can be maintained in such a state of health that they are able to participate in, and enjoy, some of the pleasures and entertainments of those who are not so grievously afflicted.

## THE FOOD OF THE COUNTRY.

*To the Editor of* THE LANCET

SIR,—In reference to your note in *THE LANCET* of Feb. 20th with this title the sad truth seems to be that the French partly, and we ourselves in a greater degree, have lost the hearty intelligent zest of our forefathers; we have become less critical; we take less trouble with our meals, think about them less, talk about them less, read about them less. In what kitchen now is the carp, "that is so curious to be caught," turned, as Izaak Walton directs, into "so curious a dish, as shall make him worth all your labour and patience"? Sad lines for the English gourmand are those that follow. Where now is the popular writer who rhapsodises over meals like a Dickens or a Disraeli, revels in them hugely like a Sala, philosophises over them like a Peacock? Alas, the pleasures of the table have ceased to provide good "copy"; instead, and it is as if we were a nation of invalids, we have columns in the newspapers devoted to vitamins and peptones and such dark matters, which may intrigue the public, but bore woefully those who know something of the subject. For many things are as essential to a meal as vitamins, or, which is the same thing, wholesome food. Obviously, the better the food, the better for those that eat it; but that is only the alphabet of the language of real dietitians, and any grown man, not mentally deficient, knows well enough what food or substance will "agree" or "disagree" with his internal mechanism. "Victims of indigestion," Brillat-Savarin roundly declares, "are those who know not how to eat." The gourmand knows more than simply how to eat. As we eat to live, so to live well we must eat well; if we would enjoy life we must enjoy our eating; and this is a higher ideal than a mere combination of nourishment and good digestion. Breakfast, on working days, may pass if it attains those salutary ends; the mid-day meal, if money-getting is the order of the afternoon, may also be severely practical; but dinner at the day's end should provide an intellectual no less than a physical recreation, and a man should rise from it refreshed alike in body and soul.

The strictly necessary foundations of such a meal, besides good food, are good cooking and prompt service; good wine, if the occasion warrants it; congenial company; and cheerful surroundings. I am perfectly aware that much of this is unattainable to-day, for nearly all of us as a *routine* —I set it out as an *ideal.* Many a dinner is eaten as a ceremony lacking one or more of these essentials; and if it is difficult to decide whether one is more important than another, this much is certain, that for each that is lacking the cost is a proportionate loss of recreation. Luxury, says Savarin, is by no means necessary (though he is far from decrying it in general); it costs little more to eat good food than to eat bad; the company and surroundings are within the reach of most men; in the matter of wines, Prof. Saintsbury's "Notes for a Cellar Book" are an unfailing guide. Cookery, whether regarded as an art, a science, or a hobby, is something that may be learnt, or at the least something that any man may learn to appreciate; but if he learns to cook ever so modestly, it is to his advantage; to have fried an egg as well as it can be fried is a step towards detecting the peculiar excellence of the wing on which a partridge rests its weight during its hours of sleep.

But with all this, the essence of good eating has yet to be named. It is best conveyed, perhaps, in the word "gusto." What matters above all is the spirit in which a man approaches his meals. They should be approached, at least once in the day, not as an inevitably recurring feature of the business of living, but as a joyous rite, a ceremony of thanksgiving. For good things, said the sage, were created for good folk; else we should be forced to conclude, profanely, that God created them for sinners.

We are a nation of individualists, and there are gourmands still in our midst; and it is, or should be, well known that they are among the happiest and most contented of mortals. But in a thousand restaurants, so-called, and in a million homes, the word of St. Savarin is daily ignored; and there should be a national recognition of the truth, that *gourmandism is not gluttony; when a national habit of* deliberately enjoying "good cheer" (to use a fine phrase that is in danger of dropping out of the language) would follow. I am, Sir, yours faithfully,

Feb. 25th, 1926. BON-VIVANT.

## ADRENALIN FOR PARAPHIMOSIS.

*To the Editor of* THE LANCET.

SIR,—Some little time ago I had occasion to write to the makers of "Adrenalin," and mentioned that I had found their preparation useful in cases of paraphimosis, and they informed me that it was, to them, a new use of the substance. I therefore venture to suggest its use in such cases; the swollen and congested mucous membrane and glans become much smaller under gentle pressure after being well moistened with the "Adrenalin," and reduction is then accomplished.

I am, Sir, yours faithfully,

Feb. 25th, 1926. M.B.

## THE STUDY OF HYGIENE.

THE reception held on Feb. 25th at the Institute of Hygiene was a useful reminder of the patient work that is always being done, largely behind the scenes, to improve living conditions in this country. The Institute was founded in 1903, and its work has been steadily growing ever since. The public owes it much for its promotion of the study and practice of everything that makes for healthy, clean, and efficient living. Its membership includes a great many foreign authorities on public health. It convenes conferences on important questions of communal hygiene, organises lectures by medical and scientific men, and founds scholarships. Some of its most important work is directed against adulteration and false description, and it examines proprietary foodstuffs in its laboratories and issues a diploma to manufacturers whose products *conform to its standards; this* guarantee expires at the end of every year. The Institute maintains a large museum (with a permanent staff of demonstrators), at its headquarters at 28, Portland-place, where anyone interested may inspect samples both of healthy and injurious articles of food, drink, and clothing. The hall-mark of the Institute is now becoming familiar to the general public, and makers regard it as a valuable possession.

The guests whom Sir Thomas Oliver received on Feb. 25th saw, besides the permanent exhibits, a large number of interesting additions. The infant section, conducted by the Central Council for Infant and Child Welfare, showed photographs of the work done at centres and hospitals, with educational appliances and propaganda pictures, and the demonstrations of cooking in the domestic section were popular. Microscopes with slides of food adulterants and parasites were shown, and a demonstrator from a firm manufacturing chemical apparatus gave a display of practical glass-blowing. Amongst the visitors was a group of foreign public health officers who are studying conditions and methods in this country under the auspices of the health department of the League of Nations.

## ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.

"OUR main building is 100 years old, and the site does not easily lend itself to expansion. Our accommodation is taxed to breaking point and a vast amount of work will have to be done if the hospital is to be made worthy of the county." So runs the annual report presented to the governors of the Royal Sussex County Hospital on Feb. 18th. Brigadier-General d'A. C. Brownlow, the chairman, said that the governors had engaged the services of Colonel D. J. Mackintosh to advise them on future extension. His scheme was divided into three parts, the first of which had been approved. This was the enlargement of the nurses' home and the building of an annexe for domestic servants. The second part was the construction of more wards, or, alternatively, of a recovery home, whilst the third was a plan for general improvement and expansion of the existing departments. General Brownlow said that on the day before that meeting there had been 222 cases in hospital, which had left only three beds for emergencies and casualties. There was a waiting list of 117. Thanks to rigid economy and a very close supervision of all expenditure, the total income had exceeded expenditure by £1,153, but the annual subscriptions, despite many urgent appeals, showed an increase of only £56. "We are up against a mountain of apathy," General Brownlow declared. At certain times there was a good deal of enthusiasm, but it was usually confined to a very small section. The governors placed on record the loss the hospital had sustained by the death of Dr. J. F. Gordon Dill, honorary consulting physician. "Dr. Dill's services to the hospital extended over a period of 36 years. He will always be remembered as the founder of the Sussex Provident Scheme. His shrewd and ready advice is much missed in our counsels." Lord Leconfield, lord-lieutenant of the county of Sussex, was elected President for the year.

## INFANT WELFARE IN THE FEDERATED MALAY STATES.

IN the annual report of the infant welfare centre at Kuala Lumpur, Dr. Josephine Were, the medical officer to the centre, is able to point to satisfactory progress in many directions during the year 1921. The centre is primarily an educational institution, providing advice and teaching for young mothers of many nationalities in the care and management of their infants. The teaching is largely individual, since the mothers, especially the Chinese and Malays, are both ignorant and superstitious. The prejudice against allowing the babies to be weighed is gradually being overcome, but there is still a good deal of difficulty in getting the mothers to believe in the necessity of a daily bath for their infants, and an even stronger objection on their part to removing a charm. One such charm consisted of a dog licence bearing the inscription "1915. Selangor, one dog. 1609."

Antenatal work is steadily going forward, the number of expectant mothers attending the antenatal clinic having been nearly trebled during 1921. Another very satisfactory advance is the almost entire disappearance of the prejudice against the visits paid to the homes by the health visitors. This health visiting is particularly valuable in bringing mothers and babies in remote districts into contact with the centre.

Apart from the work of the infant welfare centre itself, the most valuable propaganda work undertaken during the year was the infant welfare exhibition and the baby competition at the Malayan Agri-Horticultural Exhibition, held at Kuala Lumpur. Large numbers of Asiatics of all classes visited the exhibition and displayed the keenest interest in it. The baby competition, which was the first of its kind in the Federated Malay States, was also a marked success, and proved to be the most useful propaganda work so far undertaken.

THE SECOND[*] (1926)

# Milroy Lecture

ON

# EXPERIMENTAL EPIDEMIOLOGY.

*Delivered before the Royal College of Physicians of London on March 4th*

BY W. W. C. TOPLEY, M.D. CAMB.,
F.R.C.P. LOND.,
PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF MANCHESTER.

IN the preceding lecture a brief description was given of the general character of experimental epidemics among mice, and of the effect of adding susceptible to infected animals in various ways and at different rates. In the present lecture I propose to discuss such data as are available with regard to the factors concerned in bringing about the phenomena observed.

There are two principal participants in the struggle which underlies any epidemic of infective disease, the specific parasite and the animal host. It is convenient, for the purposes of discussion, to consider separately the factors which may vary in connexion with each of these, though this separation is extremely difficult to make in practice, and this difficulty forms one of the chief obstacles to a better understanding of the actual course of events.

The important variables in the case of the parasite may be supposed to be concerned with dosage and with pathogenic power; but it is far from easy to define either of these factors as they are concerned in the natural spread of disease from host to host, and still less easy to give them quantitative expression. It is my personal belief that the facile, but uncritical, use of such terms as dosage and virulence has done much to confuse the issues.

### *DOSAGE.*

It is usual to apply the term "dose" to the number of viable bacteria received by an animal host during an interval of time so short that the reception may be regarded as a single event; but very little consideration will show that such a definition cannot be employed in describing the course of events during the natural spread of disease among an infected herd. Dosage, in this sense, cannot be expressed as a quantity of bacteria, for we are not concerned with an isolated event, the reception of so many bacteria by a particular mouse. It can only be expressed as a probability, the chance that any one individual among the population at risk will, within a given time, receive a given number of bacteria.

Since we are concerned not with a single event occurring in a small interval of time, but with a possible succession of events covering weeks, months, or years, we must consider the possible effects of the order of doses, as well as the total dosage received in any period of time; and there is every reason to believe that a small dose of the specific bacterium, followed after an appreciable interval by a large dose, may have a very different result from that produced by an initial large dose, whether followed or not by subsequent smaller doses. In this connexion we must also take into account the rate at which a series of doses are received, a question which has been discussed by Dudley,[33] in connexion with naturally occurring outbreaks of diphtheria. His views as to the part played by the velocity of infection raise issues of the greatest interest and importance.

We must also realise that the functional significance of dosage may differ widely when we are considering, on the one hand, the natural intake of bacteria as by ingestion or inhalation, and, on the other, the introduction of bacteria directly into the tissues by inoculation. Defence mechanisms come into play in the former case, which are circumvented in the latter. It is probable that, in naturally occurring infection, many interrelated factors are concerned, and that these may vary independently, so that the actual event, in any particular case, *will be largely a matter* of chance, unless the dose received be so large as to overwhelm all possible resistance, or so small as to be inoperative under any circumstances. It may be that repeated small doses, within certain limits, will be more effective than a single larger dose, since there will be a succession of trials, each of which may succeed or fail. If, however, these trials are not independent, but the chance of success or failure of any one of them is determined to some extent by the results of previous trials (and this is almost certainly the case), then the problem becomes exceedingly complex, and the definition or measurement of effective dosage can hardly be achieved.

In the present state of our knowledge we can only speak of dosage, as it affects the events within an infected herd, in the most general way, remembering that it must in any case imply a chance of something happening, and not the quantitative expression of an actual isolated event.

### VIRULENCE.

Another variable in relation to the parasite is its power of establishing itself in the body of an animal host, and of producing disease and death when so established. This power is often referred to as virulence, but, as I have emphasised elsewhere,[*] this term as at present used is inadequate and misleading. There are at least two factors involved: the ability to proliferate at the point of entry, for instance, in the naso-pharynx or in the intestinal tract of the host, and the ability either to produce *some toxin at the site of local proliferation or to* invade the tissues and produce sickness or death by a generalised infection. We have no right to assume, a priori, that these biological properties are always highly correlated, that an organism which is capable, once it has gained access to the tissues, of causing a rapidly fatal septicæmia or toxæmia is also endowed with those properties which will enable it to spread readily from host to host among an infected herd. It is important, therefore, when we attempt to measure any biological character of the parasite with the object of defining the rôle of this factor in the epidemic spread of infection, that we should first determine *as precisely as possible what it is that we are measuring*. The term "virulence" is so firmly established in the medical vocabulary that it seems hopeless to replace it; moreover, if used in its literal sense of poisonousness, without any implication as to the particular lethal mechanism involved, it serves a useful purpose. It will be used here in this general sense, implying simply the power to produce death of a particular species of animal within a specified time-limit.

### HERD-RESISTANCE.

When we turn to the variable factors in connexion with the host, it is usual and convenient to group *together all those characters* which play a part in determining the occurrence, course, and outcome of a microbial infection, once the parasite has gained access to the body, under the general terms "resistance" or "immunity." At the moment we must be content with some such vague description of the sum total of the host's defensive powers, but there is one point which needs immediate emphasis.

Most of us who have been concerned at all with the problem of immunity have been accustomed to take the individual as our unit. When we take as our unit not the individual but the herd, entirely new factors are introduced. Herd resistance must be studied as a problem *sui generis*. One factor peculiar to the development of communal as opposed to individual immunity may be referred to here. A herd may clearly increase its average resistance by a process of simple selection, by the elimination through death of its more susceptible members. The initial distribution of resistance among the population at risk will almost certainly be uneven, and it will probably vary with time, since there is no reason to suppose that the resistance of any individual host will remain constant throughout the course of an epidemic. That some process of active immunisation will be associated with the occurrence of non-fatal infection may safely be assumed, though its degree and importance may be very difficult to assess, so that we must allow for the possibility that the spread of infection which is killing some of our hosts is immunising others. Here, again, just as the factor of dosage, as it intervenes in the phenomenon of herd infection, can only be expressed in terms of probability, depending upon the distribution of the parasite, so the resistance of the herd at any given moment will be determined by the frequency distribution within it of individuals of varying orders of susceptibility.

---

[*] The first lecture appeared in THE LANCET last week.

A very imperfect analogy may help to depict the position. Suppose we take a number of stakes of different thickness, plant them in the ground and expose them to bombardment with stones of varying size flung from catapults of varying strengths. After a certain time we shall find that a number of the stakes have been broken. This will not have happened to many of the thicker stakes, but other survivors will consist of thinner stakes, around which ineffective missiles have formed a protective armour. Survivors of the latter class are in a precarious state; subsequent bombardment may displace the protective heap, and perhaps add its impetus to that of the new missile. Survivors of the former class may eventually be destroyed by missiles of sufficient momentum. At any given moment many of the stakes still standing will owe their survival to chance escape from fatal impacts. On the whole the fact that, in our experimental work, we have nearly always found that the oldest survivors of series of epidemics ultimately died of the specific infection is in favour of the view that the way the shots fall, rather than the thickness of the stake, is the important factor; but since our only criterion of relative thickness is, in practice, whether the stake falls or not, judgment remains difficult.

### OTHER FACTORS.

It should be emphasised here that there is no justification for assuming that the quantitative and qualitative relations between the parasites and hosts are the sole determinants of the epidemic spread of infection. There are excellent reasons for believing that other factors may play a decisive rôle. It is, of course, the main object of such experiments as those we have carried out to reduce the number of such extraneous factors to a minimum; but there is a limit beyond which conditions cannot be simplified, and it may well be that some of the extraneous factors which have not been eliminated may play an essential part in the phenomena observed. It is, for instance, very possible that other micro-organisms, in addition to the specific parasite of the disease under investigation, may exert an important influence on the course of events. It is certain that innumerable bacteria and other organisms must pass to and fro from host to host under the conditions existing in these experiments, and we know of many examples in human and animal diseases in which double infections appear to play a decisive rôle. Other factors, such as variations in diet when these occur, or the ingestion or inhalation of particular toxic substances, may clearly be involved, and the possible part played by insect vectors of infection may have to be taken into account in particular instances.

In the light of these general considerations, we may briefly consider the data which have been yielded by experiment.

### EXPERIMENTS ON DOSAGE.

As a preliminary to studying the influence of dosage in the natural spread of bacterial infection, it is necessary to obtain some idea as to the effect of variations in the number of bacteria received by the host in the experimental infection of individual mice. It is frequently assumed that the relation between dosage and death in such experimental infections is a very simple and direct one, so that it is an easy matter to determine the minimal lethal dose of any pathogenic organism and to compare the virulence of two cultures of a given organism by determining the minimal lethal dose of each of them. It may, however, be noted that such measurements have generally been made on organisms which produce a distinctive toxin or bring about a lethal result by causing a rapidly fatal septicæmia, and which in either case are not natural pathogens of the experimental animal employed.

It is rash to assume that the same relations will hold true in the case of bacteria which naturally attack the host species chosen for experiment, and are known to give rise to acute or chronic disease or to a condition of latent infection. Lockhart, working in my laboratory, has recently made a careful study of the effect of variation in dosage on *B. aertrycke* infection in mice. His complete report is about to be published elsewhere,† but I am permitted to refer to some of his results.

His own experiments were in all cases concerned with the results of intraperitoneal inoculation, but he collected from the literature a large number of experiments in which this organism had been administered either intraperitoneally or per os, including a very large number recorded by Webster, a smaller number by myself and my colleagues, and a few reported by Neufeld, Lange, and others. To these were added the results recorded in many unpublished experiments carried out in my own laboratory. The relevant figures are recorded in Table III. It is obvious that large fluctuations in dosage, over a wide range, may make relatively little difference in the resulting percentage mortality. If we consider dosage in the wider sense, which has been outlined above, it is far more difficult to obtain any reliable data. Amoss,[21] in the communication to which we have already referred, lays considerable stress on the influence of dosage in the epidemic spread of mouse-typhoid, and regards variations in this factor, together with variations in the biological properties of the parasites, as probably determining the course of events. An increase in dosage is assumed to be an inevitable result of the contraction of the specific disease by the more susceptible mice, and this assumption is a very natural one, if we use the term "increase in dose" to mean an increased chance of any mouse at risk ingesting the specific bacterium. No attempt, however, is made to measure this increase in the concentration of *B. aertrycke* in the cage.

TABLE III.

| Dose. | Per os (collected). |  | Intraperitoneal (collected). |  | Lockhart. |  |
|---|---|---|---|---|---|---|
|  | No. of mice. | % mortality. | No. of mice. | % mortality. | No. of mice. | % mortality. |
| $10^8$ | 108 | 41 4 | — | — | — | — |
| $10^7$ | 111 | 63·0 | 154 | 100 | 400 | 90·75 |
| $10^6$ | 111 | 42 0 | 149 | 98 | — | — |
| $10^5$ | 36 | 22·2 | 211 | 95·7 | 400 | 70·0 |
| $10^4$ | 43 | 23·5 | 125 | 76 5 | — | — |
| $10^3$ | — | — | 59 | 86 6 | 400 | 59·75 |
| $10^2$ | — | — | 43 | 46·4 | — | — |
| 10 | — | — | — | — | 400 | 30·75 |

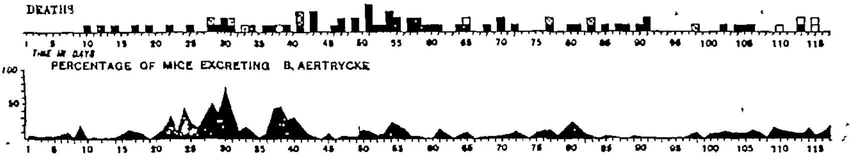
In one of our own experiments[13] we have carefully followed the daily excretion of *B. aertrycke* by each mouse in a herd among which mouse-typhoid was spreading, and to which one normal mouse was added daily. The technique employed gave roughly quantitative results, so that we were able to estimate the copiousness of the excretion in each case as well as its actual occurrence. Chart 9 records the more important data obtained. On the upper base line are recorded the daily deaths in the same manner as in the earlier charts. Below is recorded, for six days out of every seven, the percentage of the mice at risk which were excreting *B. aertrycke* in their fæces. It will be seen that the main wave of mortality is preceded, at a considerable interval, by a marked rise in the excretion-rate, and that this excretion-rate falls while the epidemic is gaining force. It is clear from this experiment that, so far as mouse-typhoid is concerned, there is, during the pre-epidemic phase, an increasing probability that any given mouse will, within any assigned interval of time, ingest a certain number of *B. aertrycke*.

---

† Jour. of Hygiene, xxv., 50.

With regard to pasteurellosis, we have at present far less information as to the relation between dosage and death in the individual mouse, and none at all as to the carrier-rate in an infected herd. Such data as we do possess on the former point suggest that, here again, variation over a wide range in the number of bacteria received by an individual host as a single dose has relatively little effect in determining the outcome of the resulting infection.

CHART 9.



### EXPERIMENTAL STUDY OF VIRULENCE.

In an extensive series of experiments, in which mice were infected with *B. aertrycke* either by intraperitoneal inoculation or by injection into the stomach through a metal catheter, Webster[34-36] obtained results which led him to the view that variations in the virulence of the bacterial parasite played little, if any, part in the epidemic spread of mouse-typhoid. He concluded from his results that any one strain of *B. aertrycke* retains its virulence at a constant level over long periods of time, when subcultured on the ordinary laboratory media, and that no evidence could be obtained of any significant increase in virulence when a given strain was passed from mouse to mouse.

The investigation carried out by Lockhart, to which I have already referred, has indicated very clearly the difficulties to be faced in comparing the virulence for mice of two or more strains of *B. aertrycke*. Paying due attention to the probable errors of sampling, Lockhart found that strains of *B. aertrycke* might show a marked decrease in virulence, as judged by intraperitoneal inoculation, after repeated subculture in broth; that different strains, with a common derivation within a period of a few years, but isolated from different mice and under different circumstances, might show significant differences in virulence; and that mouse-to-mouse passage might produce a significant increase in the virulence of a given strain, although such an increase could not be produced with any constancy. For the details of Lockhart's experiments reference must be made to his report, now in course of publication.

TABLE IV.

| Strain of *B. aertrycke* | No. of mice fed. | Total deaths. | Specific deaths. | Total No. infected.* | Strain of *B. aertrycke*. | No. of mice fed. | Total deaths. | Specific deaths. | Total No. infected.* |
|---|---|---|---|---|---|---|---|---|---|
| Pl.19.v | 20 | 11 | 11 | 13 | A 52 | 20 | 1 | 1 | 6 |
| | 20 | 15 | 11 | 15 | | 20 | 1 | 0 | 7 |
| | 20 | 13 | 13 | 13 | | 20 | 2 | 0 | 5 |

* This includes surviving mice from whose spleens *B. aertrycke* was isolated post mortem.

In Table IV. are set out the results of testing two of our own strains of *B. aertrycke* by administration to mice per os. Suspensions of growths on agar were made in Ringer's solution and administered by allowing a few drops of a suitable dilution to fall into the open mouth of each mouse from a calibrated dropping pipette. Each strain was tested on three separate batches of mice, each batch consisting of 20 animals, in order to determine the deviation in the percentage mortality due to chance variation. The mice were observed over a period of 28 days, and the survivors were then killed and cultures made from their spleens.

It is obvious from the table that strain Pl.19.v. is more virulent than strain A 52, since the difference in the mean percentage mortality in the two groups is well beyond the probable error of sampling indicated by the deviation within each group. It is obvious also that the strain which is more virulent produces a higher percentage of total infections, lethal and non-lethal combined, but that this difference is not so great as the difference in percentage mortality. The fact that strains, which are relatively avirulent, may still produce a high proportion of non-lethal infections, has been clearly indicated in Lockhart's experiments.

It should perhaps be emphasised that the variations in the power of producing death, to which we are now referring, have not been related to any observable variations in colony formation, or in the mode of growth in liquid media. That rough variants of *B. aertrycke* occur has been demonstrated in the course of earlier experiments. The strains examined by Lockhart and by ourselves in the present series were all of the smooth variety.

Our results have therefore led us to a conclusion different from that reached by Webster. They indicate that significant variations in the virulence of *B. aertrycke* for mice may occur under various conditions. Whether or not such variations play any rôle in the epidemic spread of mouse-typhoid is a question which still awaits an answer.

With regard to variations in the virulence of *Pasteurella muris*, far less evidence is available than in the case of *B. aertrycke*; but the few experiments which we have performed leave little doubt that such variations occur. There is here no conflict of evidence between the results which we have obtained in mice and those which Webster[40-44] has obtained with pasteurellar infection in the rabbit. Here, again, the significance of such variation in the epidemic spread of the infection remains undetermined.

It has been emphasised above that biological characters of the parasite, other than virulence as here defined, may play an important part in the epidemic spread of infection. We have as yet no means of measuring such characters, so that we cannot detect variations if such occur.

### EXPERIMENTAL STUDY OF HERD-RESISTANCE.

In considering the part played by the relative resistance of the animal hosts, we may first inquire whether there is any evidence that the mice, which have survived exposure to risk during the course of an experimental epidemic, show a greater average resistance to infection with the causative organism than that possessed by a similar sample of normal mice.

The first experiments bearing upon this question were concerned with the spread of mouse-typhoid. They were carried out by initiating an epidemic of this disease among a herd of mice, allowing the epidemic to subside, waiting for a further six weeks, and then adding normal mice to the survivors in the proportion of 4 to 1. The course of events was then observed for a further three and a half months, and the deaths among the survivors and added mice were recorded. One such experiment is recorded in Chart 10. The initial epidemic and the secondary wave of mortality, which occurred some weeks after the addition of the normal mice, are fully recorded.

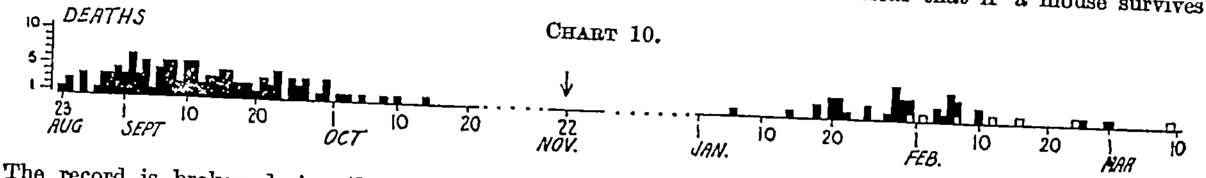


CHART 10.

The record is broken during the quiet interval to economise space. Each black square corresponds to the death of an added mouse. Each white square corresponds to the death of a survivor from the original epidemic. It is clear that, in the secondary wave of mortality, the newcomers were first affected. It was only towards the end of this secondary epidemic that the survivors from the original outbreak succumbed to the disease. When the experiment was discontinued 39 out of 44 newcomers had died, a mortality of 88·6 per cent. Among the survivors the deaths numbered 7 out of 11 mice, or 63·6 per cent. It is, however, the time-to-death rather than the total mortality which must be regarded as significant, since the numbers exposed to risk were small. The deaths of several survivors during the later stages of the secondary epidemic suggest that the relative resistance possessed by these animals, which enabled them to withstand the earlier stages of the secondary spread of infection, was insufficient to ensure their survival over a more prolonged period.

These observations were closely paralleled by the observations of Amoss,[21] to which reference has already been made. In the experiments in which he added normal mice to a population infected with mouse-typhoid he found that the death-rate among the added mice was always greater than among the survivors from the earlier periods. The occurrence of numerous deaths among these surviving mice, after long periods of exposure, showed that their increased resistance did not ensure them against a fatal attack of mouse-typhoid during the later stages of the epidemic.

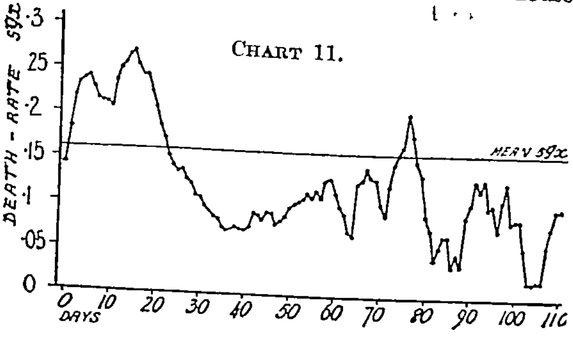

CHART 11.

With regard to pasteurellosis, the available data give a clear answer to the main question at issue. In the experiments which Dr. Greenwood and I have carried out on this disease the death-rates after varying periods of exposure to risk have been calculated for each epidemic. Chart 11 shows the fluctuation in the death-rate, calculated as the probability of dying from pasteurellosis within the next five days, for all mice in the experiment in which three normal mice were added to the cage each day. The horizontal line indicates the mean value of this death-rate. It will be seen that the probability of dying within the next five days at first rises steeply, reaching a first maximum on the fifth day, and a second and higher maximum on the fifteenth day. It then falls steeply, and from about the thirtieth day onwards the death-rate runs a general course well below its mean value for the whole experiment. There are, however, marked fluctuations. The death-rate rises and falls steeply, but never approaches the level attained on the fifteenth day, and only once exceeds the mean value during the period covered by the chart. It is clear that if a mouse survives exposure to risk for the first 30 days its chance of dying within a short interval of time has markedly decreased, or conversely its expectation of life has improved. This must mean that its resistance to the average force of mortality existing in the cage is greater than the average resistance of more recently added animals. Whether the later fluctuations are significant, and their meaning if significance be established, are questions which cannot yet be answered. The relatively small numbers at risk during the later periods of exposure do not allow us to lay much stress on these movements, but they indicate that, as in the case of mouse-typhoid, prolonged exposure to risk is no insurance against a fatal attack of pasteurellosis.

These results prove that the *average* resistance of the survivors of a herd which has been submitted to the action of an epidemic of mouse-typhoid or of pasteurellosis is raised as the result of the experience through which they have passed. Is there any evidence that the resistance of each or any of the surviving individuals has also been raised? In other words, has the herd-immunisation resulted purely from selection, from the elimination by death of its more susceptible members, or have some proportion of the individuals of which the herd is composed passed through an immunising process? It is natural to suggest that the two processes are probably combined, that some form of non-fatal infection leading to increased resistance is involved, and that such sub-acute or latent infection is more likely to be established in those mice which are endowed from the outset with a relatively high grade of resistance. Such a priori assumptions, however, can serve only as working hypotheses, and it is in any case necessary to separate these two factors as clearly as possible and to assess their relative importance.

The obvious starting point of our inquiry is to determine the normal variation among mice of resistance to infection with the causative organism concerned, but this is no easy matter. In the case of *B. aertrycke* infection, the large series of experiments carried out by Webster afford a mass of carefully collected evidence which is seldom available in investigations of this kind. Proceeding by the method of intrastomachal inoculation, Webster[26-30] has infected very large numbers of mice with a constant dose of *B. aertrycke* and has observed the subsequent course of mortality. In this way he has been able to construct a curve showing the daily progress of mortality among the infected animals and the percentage of survivors at the end of the period of observation, which has usually extended over 60 days.

As the result of testing numerous samples of normal mice, each containing between 20 and 50 animals, he concludes that the time distribution of deaths and the final percentage of survivors are constant within narrow limits for any one strain of inbred mice. From a careful survey of the records contained in Webster's reports, and from the results obtained by Lockhart, it appears to us that the actual deviations encountered are quite considerable. In constructing this curve, which he refers to as the "standard curve" for any strain of mice, Webster has plotted percentage mortality against time. It is clear that the figures could be plotted as a frequency curve showing the proportion of the total deaths occurring on each day. As we shall see, Webster makes use of such a curve in discussing the significance of his results.

It is clear that Webster's results present a record of the variations in the number and time distribution of deaths among normal mice, following the particular method of infection employed, which is of the greatest value when we wish to compare the fate of two samples of mice under different experimental conditions. Whether this is necessarily a record of the normal variation in *innate* resistance within the sample is, perhaps, not quite so certain. It may well be so, and such an assumption seems very natural, but it is necessary to inquire whether these differences may not be due in part to chance factors or to some transient physiological condition, so that a mouse which showed more than average resistance when tested at one time might show less than average resistance if tested at another. It is, for instance, not unlikely that the result of inoculating a bacterial suspension directly into the stomach may be determined in part by the physiological condition of that viscus at the moment when the suspension is introduced. It is quite probable that the outcome of an intraperitoneal inoculation may be influenced by the temporary position of the omentum or by the subsequent movements of this structure, which appear themselves to be governed by the movements of the abdominal wall and of the intestines. More general factors, such as fatigue or the existence of some unrelated infection, may account for a temporary variation in the normal resistance towards the particular parasite injected.

We cannot solve this question by direct experiment, because the successive trials would not be independent. It is evident that any mouse which had survived a single infection with a particular bacterium might, as a result of that experience, possess an altered resistance to subsequent inoculation of the same organism. It is clear, however, that if simple selection is to be effective in increasing the average resistance of a herd, the mice which have survived any given exposure to risk must have done so in virtue of lasting characters, which will enable them to withstand further exposure, and not because of some transient condition or chance event which will leave them, on the average, as susceptible as their fellows.

Webster has sought evidence of the existence of an innate and heritable resistance to enteric infection along other lines. He has carried out experiments in selective breeding [33] [34] from the results of which he concludes that it is possible, in this way, to obtain strains of mice more resistant or more susceptible than unselected animals from the parent stock. For details of these experiments reference must be made to his reports, but the results recorded do not appear to us to form an adequate basis for any final conclusion, partly because the samples tested in each generation were very small, and still more because there is no evidence that the increase in resistance or in susceptibility becomes progressively more marked in successive selected generations.

Webster and Pritchett,[35] [36] as the result of a large series of experiments, have arrived at the conclusion that strains of inbred mice show marked differences in their resistance to mouse-typhoid. Lockhart, who has recently analysed these results, has pointed out that the differences between the mean percentage mortalities observed in the different strains of mice, approximate so closely to the standard deviations of the percentage mortalities observed in different samples of the same strain, that the results cannot be regarded as certainly significant

We are left, then, with our main question unanswered, in the sense that it has not, at least in our view, been clearly demonstrated that there is an innate variation in the natural resistance of mice to a particular bacterial infection of such a nature and degree that a selective increase in the average resistance of the herd would inevitably result during the passage of a wave of mortality due to the bacterial parasite in question. We do not, of course, suggest that there is any evidence against the existence of such innate differences in resistance; indeed, we should be surprised if further investigation showed the part played by this factor to be negligible or unimportant. The recent experiments of Hirszfeld [45] on the inheritance of immunity, or immunisability, to diphtheria offer suggestive analogies. For the moment the only possible verdict appears to us to be "non-proven."

Turning to the alternative hypothesis, the active immunisation of individual mice during the progress of an epidemic, with a resulting increase in the average resistance of the herd of which they form a part, the available data allow us to arrive at a rather more definite conclusion, at least, in the particular case of mouse-typhoid. Numerous experiments have been performed on the immunisation of mice by the administration of dead or living cultures of *B. aertrycke* by Webster, Neufeld, Lange and Yoshioka, ourselves, and others. Webster's series of experiments have been particularly thorough and extensive. The available data on this question have recently been summarised by Neufeld,[46] and by Topley and Wilson.[14]

We are not for the moment concerned with the effect of the administration of dead organisms. Confining our attention to the results of administering living cultures by various routes, we find that there is ample evidence that mice which have been so treated, and which have survived the treatment, are more resistant to subsequent infection than are normal controls. But, here again, we cannot altogether escape the horns of our dilemma. Are these treated and surviving mice more resistant than the controls because they have been immunised, or because their originally high resistance has enabled them to withstand the original infection? The data available do not allow us to come to a conclusion on this point which is statistically unassailable, but a careful survey of the protocols of the experiments referred to strongly suggests that some part at least of the increased resistance is due to active immunisation. In some experiments, for instance, the surviving mice have withstood a dose of *B aertrycke* which has sufficed to kill all the inoculated controls, so that it is difficult to ascribe their increased resistance to selection alone. An even more important consideration, in our view, is the fact that it has been clearly demonstrated that the animals which have survived experimental inoculation have not, for the most part, escaped infection but have resisted it, and are in fact harbouring the causative organism in their tissues. It appears to us highly improbable that the existence of such a latent infection should be without influence on the results which follow the subsequent reception by these mice of further doses of the same bacterium In this connexion we would call particular attention to the experiments which have been carried out by Morgenroth [44] and his colleagues on superinfection. In a considerable series of experiments, in which mice were infected with sub-lethal doses of particular bacteria and were subsequently reinoculated with the same, or with closely allied organisms, these workers were able to demonstrate a significant increase in average resistance among the chronically infected mice. It seems possible that we shall gain valuable information with regard to the mechanism of active herd immunisation by investigation along these lines.

If the increased resistance shown by the mice which have survived exposure to risk be due, in large part, to active immunisation resulting from a non-lethal infection, we should expect that they would show evidence of the infection through which they had passed, or which they were still supporting. Clearly the most satisfactory evidence of the existence of such an infection would be provided by the isolation of the causative organism from the tissues. In numerous experiments on mouse-typhoid the mice surviving at the termination of an epidemic have been examined post mortem and cultures have been taken from their spleens. The results obtained are summarised in Table V., together with the results obtained in the case of individual mice which have been submitted to experimental infection. In the latter series are included the results recently obtained by Lockhart. The figures need little comment. It is clear that the majority of the mice which have recently passed through an epidemic of mouse-typhoid have not escaped infection, nor completely recovered from it, but are still harbouring the causative organism in their tissues. Their position in this respect is similar to that of mice which have survived for periods of two to six weeks after the experimental administration of *B. aertrycke* by inoculation or by the mouth. Other evidence, indicative of the wide incidence of infection among the mice at risk during the epidemic spread of this disease, has been afforded by the demonstration of agglutinins for *B. aertrycke* in the blood of surviving animals. Amoss found that 37 out of 56 mice which had survived a single epidemic wave possessed agglutinins for *B. aertrycke* in their blood.

TABLE V.—*Showing the Proportion of Positive Spleen Cultures among Various Groups of Surviving Mice.*

| Group. | Survivors left alive— | Number of mice in group. | Number of mice with positive spleen cultures. | Percentage of mice with positive spleen cultures. |
|---|---|---|---|---|
| 1 | After 11 epidemics of mouse-typhoid lasting from 60 to 117 days .. . .. | 267 | 190 | 70 |
| 2 | 21 days after intraperitoneal or subcutaneous inoculation of *B. aertrycke* (moderate doses) . .. .. . | 50 | 44 | 88 |
| 3 | 14 days after intraperitoneal inoculation of $10^7$ *B. aertrycke* | 40 | 40 | 100 |
| 4 | 14 days after intraperitoneal inoculation of $10^5$ *B. aertrycke* | 114 | 109 | 95·6 |
| 5 | 14 days after intraperitoneal inoculation of $10^3$ *B. aertrycke* | 280 | 232 | 82·9 |
| 6 | 14 days after intraperitoneal inoculation of 10 *B. aertrycke* | 213 | 95 | 44·6 |
| 7 | 42 days after one feeding with $20 \times 10^6$ *B. aertrycke* .. .. | 98 | 60 | 61·2 |
| 8 | 43 days after one feeding with $2 \times 10^6$ *B. aertrycke* .. .. | 39 | 13 | 33·3 |
| 9 | 42 days after three or four feedings with $2 \times 10^6$ *B. aertrycke* .. .. .. | 59 | 39 | 66·1 |

Finally, we would draw attention to an experiment, already referred to, in which we obtained detailed records of the daily excretion of *B. aertrycke* in the fæces of all mice at risk during an epidemic which was maintained for a period of 117 days by the daily addition of one mouse to the cage. The total number of mice at risk during this period was 135, excluding 5 infected mice which were employed to initiate the epidemic. Of these, 55 were alive when the experiment terminated. Of the whole number at risk 122 yielded evidence of infection by dying of mouse-typhoid, by excreting *B. aertrycke*, by yielding a culture of this organism from the spleen when killed at the termination of the experiment, or by the presence of agglutinins in their blood. Only 13 mice failed to show any evidence of infection with *B. aertrycke* by any of the methods of examination applied. Of these, 6 mice had resided in the cage for less than 14 days when the experiment was terminated, while one mouse, whose sojourn in the cage was 27 days, was devoured by its companions and could not be examined post mortem. Thus among 121 mice‡ which had been exposed to the risk of infection for 14 days or more only 6 failed to yield evidence of a reaction to the presence of the parasite.

There would appear to be little doubt that during an experimental epidemic of mouse-typhoid the great majority of mice exposed to risk become infected within a short time of their entry to the cage, and that a high proportion of those mice which withstand such infection continue to harbour *B. aertrycke* in their tissues for a considerable period. Such survivors have been shown to possess an increased average resistance to the disease as naturally acquired. We are far from denying the existence and possible importance of simple selection based on innate differences in resistance, still further from neglecting the possibility that there may be natural variations in the capacity of mice to become actively immunised; but it seems to us that we are on surer ground in attributing some part, at least, of the relative immunity of the surviving animals to active immunisation.

## EXTRINSIC FACTORS.

We have suggested that variations in the infective power of the parasite, or in the resistance of the host, by no means exhaust the possible interplay of factors which determine the sequence of events in our herds of mice. We have as yet little information on such matters as the possible influence of microbial association, or of other factors which might result in a shifting equilibrium between parasite and host. In the case of mouse-typhoid we have carried out experiments on the possible rôle of the bacteriophage in the epidemic spread of this disease, but our results have been entirely negative.

Webster[34] has obtained evidence pointing to the importance of dietary factors in determining the incidence of infection with *B. aertrycke.* The interest and importance of such observations are obvious, but it seems unlikely that dietary factors can play any part in the fluctuating sequence of events which we have observed in our long-continued epidemics, since no change has been made in the nature and amount of the food-supply to the mice at risk.

On the basis of the evidence outlined above, we do not seem to be justified in going beyond the following conclusions.

In the case of mouse-typhoid, variations over a wide range in the size of a single dose of bacteria administered to mice by feeding, or by inoculation into the tissues, appears to have very little effect in determining the outcome of infection. There is a suggestion that the same holds true for mouse-pasteurellosis. It by no means follows that variations in the number of bacteria received by susceptible hosts during the natural spread of infection are unimportant. Under such circumstances, not only the size of individual doses, but the effect of a succession of doses, and the rate at which they are received, must be taken into consideration.

Variations in the virulence of *B. aertrycke* and of *Pasteurella muris* certainly occur. Whether such variations play any part in the natural spread of infection remains to be determined.

Mice which have survived exposure to risk during an epidemic of mouse-typhoid or of pasteurellosis show an increased average resistance to continued exposure to risk, as compared to normal mice which have not been so exposed.

When a sample of normal mice are tested by the inoculation of *B. aertrycke* into each mouse the response varies, and the variation may be studied by observing the time distribution of the deaths and the final percentage of survivors. It is not clear in how far this variable response depends on innate characters in the mice, on transient physiological conditions, or on the interaction of chance factors, so that we cannot be certain that the passage of a wave of mortality will leave survivors which were possessed, *ab initio*, of a high degree of resistance of a durable kind, and will so increase the average resistance of the herd by a process of simple selection. This problem still awaits solution.

In the case of mouse-typhoid there is ample evidence that the great majority of any given sample of surviving mice have not escaped infection, but have resisted it. A high proportion of these mice are found to be supporting a latent infection with *B. aertrycke.* There is evidence that mice which have withstood individual experimental infection with *B. aertrycke* are far more resistant than normal mice to subsequent infection with this organism. It is, therefore, probable that active immunisation, following non-lethal infection, plays a considerable part in the increase of the average herd-resistance which follows exposure to an epidemic of enteric infection.

---

‡ This figure was incorrectly given as 135 in a previous report.

It is probable that additional factors not connected with dosage of the parasite, nor with variations in the biological characters of the parasites or hosts, play a part in the spread of epidemic infection. With the single exception that a bacteriophage, active against *B. aertrycke*, seems to have little influence on the course of events in epidemics of mouse-typhoid, we have as yet no information on this aspect of the problem.

When we attempt to give quantitative expression to any of the factors which are concerned in the spread of infection during an epidemic of disease, these factors must be measured not as absolute quantities, but in terms of probability. It seems certain that chance plays a large part in the sequence of events which we have observed and described, but this sequence is sufficiently orderly to suggest that an adequate knowledge of the various probabilities involved would allow us to give a generalised description of the interactions concerned.

# An Address
## ON THE TREATMENT OF MALIGNANT DISEASE WITH LEAD.*

*Delivered before the Glasgow Gynæcological and Obstetrical Society*

BY W. BLAIR BELL, B.S., M.D. LOND.,
HON. F.A.C.S.,
PROFESSOR OF GYNÆCOLOGY AND OBSTETRICS IN THE UNIVERSITY OF LIVERPOOL; GYNÆCOLOGICAL AND OBSTETRICAL SURGEON, ROYAL INFIRMARY, LIVERPOOL, HON. DIRECTOR, LIVERPOOL CANCER RESEARCH.

*In Association with*

H. F. WOOLFENDEN, M.D. Liverp., F.R.C.S. Eng.,
SURGEON TO THE ROYAL INFIRMARY;

W. R. WILLIAMS, M.D. Liverp.,
F.R.C.S. Eng. & Edin.,
ASSISTANT SURGEON, ROYAL SOUTHERN HOSPITAL;

L. CUNNINGHAM, M.B. Camb., M.R.C.P. Lond.,
ASSISTANT PHYSICIAN, DAVID LEWIS NORTHERN HOSPITAL,

AND

S. B. HERD, M.D. Liverp.,
ASSISTANT GYNÆCOLOGICAL SURGEON, ROYAL INFIRMARY.

*Together with a Comment by*

J. G. ADAMI, M.D. Camb., F.R.S.,
VICE-CHANCELLOR OF THE UNIVERSITY OF LIVERPOOL; FORMERLY PROFESSOR OF PATHOLOGY IN MCGILL UNIVERSITY, MONTREAL.

IN previous communications the scientific views on which this work is based have been fully explained and weighty confirmatory evidence—experimental and clinical—has been adduced in support of the statements made.[1, 2, 3, 4, 5, 7] A paper concerning the toxic effects of lead administered intravenously has also been published.[6] We are now in a position, therefore, to discuss at some length our methods of procedure and our clinical results which, after all, are the ultimate test of all cancer research.

It must not be forgotten, however, that so far the treatment of our cases has been largely experimental and tentative in nature, and that, as might be expected, the results have been uneven and the failures and misfortunes many. *Indeed, we ourselves regard the results obtained in the treatment of the first 200 cases, mostly hopeless, merely as affording confirmatory support to the rest of the evidence pointing in the same direction, and not as being the outcome of a test of the merits of a new treatment.* Furthermore, we must insist that we make no claims whatsoever in regard to the general curability of cancer by the use of lead: we simply state the facts.

On Nov. 9th, 1920, the first intravenous administration of lead was given to a patient with an advanced breast carcinoma. Providentially this case proved, one of the most interesting and striking of the whole series; and the importance of the result was none the less in that it gave us the stimulus and encouragement necessary in our dealings with the numerous dreadful cases of malignant disease that soon came under our care.

In passing we cannot refrain from saying that we know of no disease that produces so depressing an effect on those continually associated with it as cancer. The pitiable plight of the patients, the pain and discomforts that follow the involvement of important organs are such as to produce a profound impression on the mind of the patient, even though she may be unaware of the nature of the disease. Unfortunately, this is sometimes known, and when the patient has reached the depth of despair, it makes it difficult to persuade her that the faintest chance remains. Standing out against this in the brightest contrast we have seen wonderful heroism, even optimism, in some of those whose chance seemed slender. We feel that we must be allowed to say so much, because it may make clear to those, even to members of our own profession who appear not to have understood, how extremely reticent we have felt it necessary to be in order not to raise false hopes amongst the millions of sufferers with this disease who are scattered over the entire world.

As stated by one of us in the previous publication,[7] we believe that evidence has been obtained in many directions confirming the correctness of the lines on which we have worked and are still working. In these circumstances the moderate success we have obtained so far in the treatment of cancer may justify the guarded publicity we now give to our clinical work, even though it still appears an impossibility that cancer should be treated empirically with lead; we have already emphasised the dangers and difficulties of our methods.[6] In short, despite the pressure brought to bear, we do not think the time is yet ripe for the general employment of lead, for a vast amount of work, experimental and therapeutical, still remains to be accomplished. We have no doubt that the preparation of lead in colloidal form for intravenous injection will be vastly improved, or lead be administered in another form; and we recognise the possibility that some other substance may be found to act in the same way as lead on malignant neoplasms, but with less toxicity towards other tissues of the body.

### METHODS OF PROCEDURE.

### *Records of the Patients.*

The work has been conducted on lines laid down at the commencement, special case-cards having been printed in order that a more or less uniform standard of detail should be obtainable. This we found of great value in summarising the toxic effects of lead.[4] On the case-cards all previous methods of treatment and the particulars of the present condition of the patient have been recorded, together with a full account of the examination of the body fluids and of any tissue removed for section. In addition, specially printed forms have been at the disposal of Prof. Ernest Glynn, who has reported on all the material submitted for histological examination. In many cases, sections sent with the patient have been re-examined and described in the light of subsequent events. Moreover, Dr. R. E. Roberts has examined radiologically a large number of the patients about whom it seemed likely that further information could be obtained by this method. Medical examinations, too, have been conducted in many cases by Prof. John Hay and Dr. L. Cunningham, and biochemical investigations by Dr. R. Coope and Dr. Cunningham. We have thus endeavoured to obtain all the evidence that would guide us in the subsequent treatment of our patients.

---

### *Indications for, and Contra-indications to, the Treatment of Patients with Lead.*

*Extent of the Malignant Growth.*—In regard to this question it may be said in general that a large amount of malignant tissue is not necessarily a bar to treatment, provided other conditions permit this course to be taken; but secondary involvements of the lung and the brain may be an absolute contra-indication. It will, moreover, be shown that serious accidents may occur when certain vital organs are affected, if the disappearance of the growth be too quickly accomplished.

*Condition of the Patient.*—The general condition of the patient must be viewed from several angles. First it is necessary to take into account the state of certain organs which, although unaffected by the malignant disease, may be subject to pathological lesions due to other causes, rendering treatment unduly dangerous; chronic nephritis is by far the most important of these lesions. Secondly, pressure on the common bile-duct by cancer of the head of the pancreas may produce a condition in the liver that makes it unwise to inject lead until the jaundice, mechanically produced in this way, has been relieved. Thirdly, we must take into consideration the constitutional state produced in the patient by long-standing malignant disease. As will be shown directly, many of our cases have died, some before treatment, others very shortly after the commencement, and, again, a number before lead in quantity considered sufficient to overtake the disease could be administered. At first we rejected *no one*—hence many unhappy incidents.

To-day we feel it is not right to prejudice any longer the method by dealing with totally hopeless cases—cases that after trial of every known form of treatment have been sent to us in the vain hope that the day of miracles is not past. At the same time it is not possible, nor humane, for us to adhere to any rigid line of demarcation. Yet, with our experience behind us, we have come to recognise those cases in which there is a prospect of relief; and by this we mean those in which the arrest of the disease may be possible, or in which there is a chance of causing the disappearance of the growth. It appears that in regard to tumours that have a good blood-supply, if the patient be in good condition, and the growth is not larger, say than 5 per cent. of the body-weight, hope may be entertained, provided we invoke, in certain cases, the aid of surgery and radiation.

In order that we may not be misunderstood it should be stated that, whenever possible, we like to remove as much of the growth as we can before commencing treatment with lead, but, of course, such a procedure is not eradicative. There is no doubt that lead, as might be expected, is quantitative in its method of action. Although we do not believe that small doses of lead increase the rapidity of the growth, as do X rays and radium, it is quite useless to give an insufficient quantity; hence our reason for wishing first to get rid of as much of the malignant tissue as possible.

### *Nature of the Preparation Used.*

From November, 1920, to April, 1921, a number of imperfectly colloidal preparations of lead were used; still some appear to have been quite effective. Nevertheless, in the incompletely colloidal state the general toxic effects on the patient appeared to be more serious and common than now, when we use the metal properly protected; but, as the method of dosage has varied, it is impossible to make an accurate comparison.

In the earlier preparations we employed lead iodide in which the iodine was obtained from thyroiodin by the action of lead on this substance. A compound of lead with hæmoglobin, which we hoped would protect the blood and the blood-forming organs, was also used. This, however, undoubtedly had toxic properties of its own, no doubt due to the hæmoglobin obtained from animals, which substance appears to be more or less generically specific. We also used compounds of lead oleate and lead "morrhuate" for intramuscular injection. These were abandoned because they appeared to be unabsorbable.

Finally, Prof. W. C. McC. Lewis and his associates, Dr. J. W. Corran and Dr. M. Jowett, found it possible to make a good electrical suspension of metallic lead in an aqueous medium with gelatin (0·4 per cent.) and calcium chloride (0·027 per cent.) by Bredig's sparking method, as described and discussed two years ago.[3] We at present employ about 20 amps., under 70 volts. The final product after centrifugalisation to get rid of particles larger than 0·2 $\mu$ is made hypertonic by the addition of sodium chloride (2·0 per cent.), potassium chloride (0·05 per cent.) and calcium chloride (0·027 per cent.), and is sterilised by boiling. The strength of this preparation, known as $S_7$, is adjusted by dilution with the sparking solution to contain 0·5 per cent. of Pb.[†] We are not yet satisfied about the stability of the preparation now used, and the physical chemists hope to improve it, and eventually to render it sufficiently stable for distribution.

It is still sometimes asked, although we have previously explained the matter, why we use a colloidal preparation. We have already indicated that lead ion is very toxic.[4] Had we pursued the question we might have discovered a preparation better than lead morrhuate for the administration of lead intramuscularly, but we are sure it would not have been so effective as the intravenous injection of perfectly protected lead. The whole object of using a colloidal preparation is to deliver the lead slowly to the highest bidder, as it were, among the body tissues—this we believe to be the malignant cell—in quantities with which they are able to deal as it is released to them. It is highly probable that our preparation dissociates quite slowly in the blood stream, and this matter is under investigation by Prof. Lewis and his associates.

### *Methods of Introduction and Dosage.*

*Intravenous Injection.*—It seems obvious that in the treatment of existing malignant neoplasia the best method of attacking the disease is through the blood stream; it is, indeed, the most rapid and inevitable way of reaching all the tissues of the body. Moreover, by the administration of a drug intravenously, we know that it is at least taken up by the tissues or immediately excreted. Drugs administered by the mouth, or injected into the tissues, are not always absorbed. Nevertheless, with regard to such growths as epitheliomata and scirrhus carcinomata of the breast, there is always present the difficulty that vessels are not in close proximity to the growing cells; indeed, this may be a contributory reason why the disease is present at all.[*] With sarcoma the matter is somewhat different, but in this disease, again, it is common to find large masses of growth inadequately supplied with blood-vessels.

---

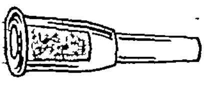
[†] Apart from the voltage, amperage, and percentage figures, which are of relative importance only, for they have undergone, and are still undergoing, frequent alteration—the figures given here being merely those recently in use—the whole method was described and discussed, as stated, two years ago in sufficient detail for anyone to have repeated and extended the work already done. It has, therefore, been a matter of considerable surprise to us to hear on all sides that the "method of preparation" has not been published. Such a statement reflects but little credit on those responsible for it, and demonstrates either that these critics have failed to read what has been published—an unpardonable omission—or that they are so ignorant of elementary physical chemistry that they have been unable to understand.—W. B. B.

As already indicated in a previous paper,[*] except at the very beginning, for about three years and a half we employed small doses not exceeding 0·04 g. of lead, and generally much less than this. Looking back we see that our earliest cases appear to have done well, but with a reduction of dosage good results became fewer and chronic poisoning more frequent. Subsequently to our work on the action of lead on the chorionic epithelium of the rabbit,[*] during which we found that the dose inevitably lethal to this epithelium was half of the fatal dose to the mother, we have employed what we describe as "massive doses."

Generally speaking, it may be said that in a patient of average size and of average susceptibility, and without hepatic or renal disability, a fatal dose of lead, intravenously administered, is in the neighbourhood of 35 to 40 c.cm. of the colloidal solution we now use—that is to say, the fatal amount of lead is a little more than 0·2 g. when administered in a single dose. It must, however, not be forgotten that patients with large tumours are less subject to the bad effects of lead than patients whose growth is small in proportion to the body-weight. We have seen patients with huge malignant growths tolerate lead in a surprising fashion, and we have, as previously stated, been able to analyse tumours from patients to whom large quantities of lead had been administered. In these investigations we found in the tumour a quantity of lead which demonstrated clearly that the greater proportion of that administered must have been attracted to it.

We observed that the administration of a total quantity of 0·27 g. of lead in repeated doses spread over a protracted period of about 18 months produced a certain cumulative toxic effect on the patient, which, as we have previously said, was difficult to combat. With the massive doses it is possible to give approximately 0·6 g. of lead in seven or eight doses during a period of four months without producing any serious ultimate consequences whatsoever to the patient. As a rule, our present practice is to give about four injections of 10–20 c.cm. of S, at intervals spread over a period of about six weeks, and subsequent doses are regulated according to the general and local conditions of the patient. Still, even at the time of writing we are experimenting with different quantities and intervals.

For the injection of this preparation, which is of a black or slatey colour, according to the amount of hydroxide and carbonate it contains as the result of contact with air, we have found the attachment shown in the figure, which we had made, and which we call an "interceptor," extremely useful; it is of glass and is fixed between the nozzle of the record syringe and the needle. The surgeon is thereby enabled to see the ascent of blood when the vein is reached; this was impossible before we used the interceptor. Those who have had an experience, such as we have, of many thousand intravenous injections, know the difficulties that may arise in the case of a fat woman.



*Ionisation.*—We have long used this method for the introduction of lead ions into superficial neoplasms. In certain cases in which there is extensive lymphatic invasion, such as is seen with carcinoma of the breast, there may be a diminution in the pain and a softening of the parts. Incidentally, we may call attention to the fact that Borrel[*] has recently shown that of all the metals used for the ionisation of rat sarcoma, lead is not only by far the most effective, but almost invariably causes the disappearance of the tumour. Dr. H. E. Annett, working with us, has obtained similar results by the ionisation with lead of this type of tumour.

There is some doubt as to the penetrating power of the lead ion in these circumstances, but we cannot disregard the results we have occasionally seen. The quantity of lead that is passed into the tissues in the circumstances in which we have used this method has amounted to 0·003 g. at one sitting of 15 minutes. In one or two cases we have ionised the tumour itself, or the site from which it had been removed by the insertion of one electrode into the mass or cavity, as the case may be.

*Intramuscular Injection.*—We shall not discuss the method of intramuscular injection which has been employed, for we have ceased to use it for the present, owing to the pain caused and to the unabsorbable nature of the material.

### ACCOUNT OF CASES TREATED.

In all 247 patients were seen in the period under review. Of these 227 have received treatment. In Table I. an age classification is given; in Table II. the types of malignant disease treated are shown; in Table III. the ultimate, or present, fate of the patients is made clear; and in Table IV. is shown the sex and the type of disease that has been benefited by treatment.

TABLE I.—*Age Classification.*

| Years. | Males. | Females. |
|---|---|---|
| Under 10 | 4 | — |
| *10–20* | 4 | — |
| 20–30 | 6 | 5 |
| 30–40 | 7 | 18 |
| *40–50* | 16 | 43 |
| 50–60 | 21 | 55 |
| 60–70 | 13 | 23 |
| Over 70 | 4 | 8 |
|  | 75 | 152 |

Number of patients: males, 75; females, 152; total, 227.

TABLE II.—*Sites of Growths and Sex of Patients.*
*Carcinoma:* Males, 53; females, 130.
*Sarcoma:* Males, 22; females, 10.

| Sites of the growths. | Cases. | Females. | Males. |
|---|---|---|---|
| Mouth and tongue | 9 | — | 9 |
| Cheek | 2 | — | 2 |
| Œsophagus | 8 | 1 | 7 |
| Stomach | 16 | 4 | 12 |
| Small intestine | 1 | 1 | — |
| Large intestine | 7 | 5 | 2 |
| Rectum | 18 | 7 | 11 |
| Liver and bile passages— |  |  |  |

### TABLE III.

*Fate of Patients: Nov. 9th, 1920–Nov. 9th, 1925.*

| | Cases. |
|---|---|
| 1. Admitted, but died before treatment could be commenced | 20 |
| 2. Died before treatment could be completed | 50 |
| 3. Died of intercurrent affections | 3 |
| 4. Died after treatment (including two deaths from acute nephritis the result of lead poisoning) | 106 |
| 5. Died as a result of extensive destruction of growth by lead | 4 |
| 6. Too recent for results to be estimated | 14 |
| 7. Complete treatment refused, but patients are living normal lives | 9 |
| 8. Disease completely arrested | 10 |
| 9. Believed cured, and treatment stopped | 31 |
| | 227 |

A brief discussion of these groups is necessary.

### *Cases which Died before Treatment could be Commenced.*

In our anxiety not to refuse any case that came to us for treatment, we admitted some who were so ill that they died during the few days devoted to the preliminary investigations of their general condition—before any lead could be administered. In reviewing the statistics of the cases treated, it must constantly be borne in mind that nearly every case which came to us had been condemned as hopeless, every other known avenue of treatment having previously been explored.

### *Cases which Died before Treatment could be Completed.*

Death took place in a large number before adequate treatment could be given, the general condition of the patients being unsatisfactory from the first. In 43 cases death occurred before 0·2 g. of lead had been administered, and many of these received considerably less than this quantity, the average amount being 0·116 g. This group should, therefore, be completely excluded from any estimation of the beneficial effects of the method of treatment under discussion.

### *Cases that Died of an Intercurrent Affection.*

The following are two examples.

CASE 2.—A female, aged 61, was admitted with a large growth in the right breast, ulcerated, and fixed to the chest wall. There was a large mass in the axilla, and the supraclavicular glands were involved. She had only five injections, making a total of 0·2 g. of lead. A very considerable improvement took place; the growth appeared to be shrivelling up, and the glands in the axilla became softer and more discrete. The patient returned home for Christmas (1020), contracted pneumonia, and died. Her own doctor, who examined the growth immediately after death, reported that it had shrunk to about one-third of the original size.

CASE 26C.—The patient was a man, 71 years of age, with four months' history of increasing dysphagia with persistent loss of weight. X ray examination showed marked obstruction at the cardio-œsophageal opening. The Wassermann reaction was negative. The total quantity of lead given amounted to 0·28 g. There was marked clinical improvement, and the patient was able to swallow tolerably well, but he died from pneumonia six months after the commencement of treatment.

### *Cases which Received a Considerable Amount of Treatment but Ultimately Died.*

This group of cases—necessarily a large one—may be viewed from two points: (1) lead had no action on the malignant growth present; (2) our methods of treatment are imperfect.

There can be little doubt, we think, in view of the clinical evidence obtained, that lead has specific action on malignant neoplasia *if it can reach the growing cells*, so we can only conclude, and indeed we know, that our methods of treatment are far from perfect, and that some of our failures are due to this cause, especially in the early cases, when we often gave too small doses, or for some reason lead failed to reach the growth in a sufficient quantity to cause arrest or disappearance.

From what has been said it will be clear that the more avascular a tumour is the less chance there is of our dealing successfully with it, unless we can induce the malignant cells to take up the lead. We have employed a variety of expedients, such as fibrolysin and thyroidin for this purpose. Nevertheless, this difficulty still remains to be overcome.

In this group two cases from our series may be taken to illustrate another difficulty. Both these patients had protracted treatment, but the total amount of lead given was not great, as at that time we were using only small amounts of colloidal lead. They both showed very definite signs of improvement, but for various reasons the patients were unable to continue the injections.

CASE 111.—The patient was a youth, 18 years of age, with advanced sarcoma of the scapula. X rays showed that the scapula was almost completely decalcified, and a portion of growth removed for section confirmed the diagnosis. After 0·13 g. of lead had been administered together with a few exposures to X rays, the tumour began to disappear, and very shortly afterwards the whole scapula re-formed and ossified, as shown by a series of skiagrams. The patient then ceased treatment for a time, but returned two months later with a small, but obvious, recurrence. In view of the fact that X rays had been helpful before, it was decided not to give the patient any lead, but to try the effect of X rays alone. The tumour did not respond, so injections of colloidal lead were again given, and a second time the tumour began to disappear and the scapula to re-form. The patient, who lived at a distance, was unable to continue the treatment, and again there was a recrudescence of the growth, metastases developed, and he died.

CASE 125.—This was a school-boy, aged 13 years, who had had his leg amputated two months previously for a sarcoma in the lower end of the femur. He was sent to us almost before the incision had healed with a recurrence in the cut end of the bone. He received 0·13 g. of lead, and X ray treatment to the stump. All the swelling disappeared, and a skiagram showed that the bone end was practically normal. He was discharged as cured. Twelve months later he reappeared, with large secondary masses in the abdomen and chest, but the condition of the stump itself was quite satisfactory. To our amazement we heard many months later that he was still alive.

In the two foregoing cases we hoped that we had effected a cure, but in both instances we were afraid to push the treatment too far owing to the youth of the patients, although neither of them showed any dangerous sign of poisoning.

Another patient, for certain reasons, was unable to carry on with the treatment; and yet another, feeling himself so well, did not come to be seen by us until it was very obviously too late to resume the administration of lead.

We do not in these remarks intend to disguise the fact that the treatment with lead definitely failed in most of the cases in this group to bring about the desired result, although it must be said that in many changes occurred in the growths which we regard as significant.

### *Cases in which the Patient has Died as the Result of Extensive Destruction of the Growth by Lead.*

In the following cases the patients died as the result of the destructive action of lead on malignant neoplasms present. There were four definite instances of this.

CASE 153.—A young man, 22 years of age, who four months previously had had a partial gastrectomy for a small pyloric tumour, which subsequently proved to be a sarcoma, when admitted to our care, had an extension of the disease in the stomach, and the tumour was then of the same size as that of a football. After the administration of 0·09 g. of lead the abdomen suddenly became quite flat and no tumour could be felt. Two more injections were given, making a total of 0·15 g. of lead. One day, just three weeks after the commencement of the treatment, the patient complained of great abdominal pain, and became very pale and collapsed. He died the same night. At the post-mortem examination Prof. Ernest Glynn found some dark fluid blood in the peritoneal cavity, and that the tumour was replaced by a large black necrotic mass of the consistency of mud. The only part of the original growth from which a section could be made subsequently was a piece which had invaded the liver by direct extension.

CASE 12.—The patient was an old man of 77 years of age who had a history of a swelling in the buttock for the previous two years. On admission he was found to have an elastic swelling of the same size as that of a cocoanut under the gluteal muscle. A small piece was removed for section and was shown to be a very vascular sarcoma. Four injections, equivalent to 0·1 g. of lead, were administered. Three weeks after the commencement of the treatment he had considerable hæmorrhage from the exploratory incision. Blood was transfused next day, but he did not recover. The tumour was exposed after death and was found to be completely necrosed in its centre, and in the large cavity formed there was a mixture of blood-clot and broken-down growth.

CASE 174.—The patient was a woman, 57 years of age, who had a postcricoid carcinoma. She was quite unable to swallow; her voice, however, was unaffected. A preliminary gastrostomy was done, and in view of subsequent events it would have been better if a preliminary tracheotomy had also been performed. We administered intravenously 0·2 g. of lead in one dose. Hæmaturia followed, but the most serious symptom was dyspnœa, which rapidly increased. Three or four days later the trachea was opened, but the patient died a few hours afterwards. At the post-mortem examination the growth was found to be very œdematous and sections showed acute necrosis of the malignant cells which were lying in an œdematous stroma of loose connective tissue.

CASE 206.—The patient was a man, aged 58 years, with a large sarcoma of the left femur. Altogether he was given 0·31 g. of lead, including an initial massive dose of 0·2 g. An incision was made in the skin and 8 oz. of blood-stained material withdrawn on the day before he died. At the autopsy the tumour was found to have liquefied, and practically the whole of the original site of the tumour was occupied by hæmorrhagic necrotic material.

### *Too Recent for Results to be Estimated.*

Nothing need be said of the cases—14 in number—in which treatment had recently been instituted.

### *Complete Treatment Refused, but Patients are Living Normal Lives.*

It is an extraordinary fact that many patients, although aware of the nature of the disease from which they are suffering, frequently refuse to continue treatment. Either they lived at too great a distance to reach Liverpool easily, or the treatment already administered has produced colic, vomiting, and other unpleasant symptoms, which they are not prepared to bear again. At the time when these figures were collected, the nine patients were living and leading normal lives. We have not had information since that date that they are doing otherwise.

### *Disease Completely Arrested.*

In a number of cases, especially when the tumour was large, the effect of treatment appears to have been that the growth was completely arrested, but did not disappear. In such circumstances the patients have shown remarkable constitutional improvement, and have increased considerably in weight, sometimes by so much as 3 st.; and symptoms, the result of the disease, have disappeared, except such inconveniences as those produced by an intra-abdominal tumour of a certain size. The arrest of growth in the case of sarcoma may be very striking, and is undoubtedly evidence of the inhibitive action of lead on the development of such tumours. It is impossible, of course, to say that there will never be a reawakening of active growth in these circumstances, and possibly it would be good surgical practice to remove the latent neoplasm. Sometimes this would be a very difficult and dangerous proceeding, and the patient undoubtedly would prefer to continue in the state of improved health she has gained rather than run the risk of a fatal issue. There are 11 cases in this group, and their future welfare will be a matter of great interest and importance.

### *Cases Believed Cured.*

It is quite impossible to define the cure of cancer. To clinicians, though apparently not to laboratory workers, it is well known that the possession of a malignant growth successfully treated by surgical or other procedures does not confer on the patient immunity from subsequent neoplastic developments. In the experience of all surgeons a number of such cases occur; consequently it is clear that every patient who is cured of one malignant growth may develop another and require further treatment. This is the first point. The second point in regard to the difficulty of estimating what may be considered a true cure is the fact that a primary growth, apparently successfully treated, may develop on the same site, or in the form of a metastasis very many years later. It is evident, therefore, that the five-year period usually allotted to the demonstration of a cure of previously existing cancer is not valid, although flattering to surgical statistics. We therefore think it right and proper to describe our cases, which are now apparently perfectly well and give no evidence of disease in any part of their body, as "believed cured."

In Table IV. the cases summarised in sections 7, 8, and 9 of Table III. are shown in respect of sex and the nature of the malignant disease from which they suffered.

TABLE IV.—*Cases in which the Growth has been Completely Arrested, or the Patient is Believed to be Cured.*

Sections 7, 8, and 9 from Table III., 50 cases.

*Sarcoma.*—Number of cases, 6 (female, 4; male, 2).

*Site of Growth.*—Female: (1) small intestine; (2) uterus (body); (3) retroperitoneal tissue; (4) ovary. Male: (5) scapula; (6) connective tissue of thigh.

*Carcinoma.*—Number of cases, 44. Female: primary carcinoma, 32; secondary carcinoma, 7. Male: primary carcinoma, 4; secondary carcinoma, 1.

*Situation of Tumour.*

*Primary Carcinoma.*

| | | | |
|---|---|---|---|
| Breast .. .. | 14 | Body of uterus .. .. | 1 |
| Cervix .. .. | 9 | Œsophagus (male) .. .. | 1 |
| Rectum (female, 2; male, 1) | 3 | Fauces and pharynx (male) | 1 |
| Ovary .. .. | 2 | Gall-bladder (male) .. | 1 |
| Pancreas (female .. .. | 1 | Adenocarcinoma of fibromyoma and pelvic cellular tissue .. .. .. | 1 |
| Vulva .. .. | 1 | | |
| Stomach (female) .. .. | 1 | | |

*Secondary Carcinoma.*

| | |
|---|---|
| Glands in neck and axilla (secondary to breast) .. .. | 5 |
| Tibia (secondary to testicle) .. .. .. .. .. | 1 |
| Ovary (secondary to breast) .. .. .. .. .. | 1 |
| Peritoneum .. .. .. .. .. .. | 1 |

Brief summaries of the histories of a few of the more remarkable of the cases contained in Table IV. may be given. It is impossible in a paper of this character to give the complete histories of all the cases.

### *Examples of Cases in which the Growth has been Completely Arrested.*

These cases give indication of complete recovery, but have not been treated for a sufficient length of time to be regarded as cured. Every one of them had relatively large growths, and in one case the mass filled up the whole of the pelvis and a large portion of the abdomen.

CASE 178.—The patient was a woman of 38, who four months prior to admission complained of abdominal pain. A mass was discovered in the pelvis, and laparotomy was performed by a London surgeon, who found a very large vascular growth filling the whole of the pelvis and most of the lower part of the abdominal cavity. On account of the danger from hæmorrhage no portion of the tumour was removed even for section. On admission there was a large soft central tumour extending above the umbilicus, irregular in outline and filling the pelvis. She came under our care in December, 1924. A further laparotomy was done, and a small piece removed for section. Examination proved the tumour to be a short spindle-celled sarcoma, probably arising in the ovary. She was given 0·15 g. of lead at one injection. This caused most distressing toxic symptoms, both gastro-intestinal and urinary. Vomiting persisted for over a fortnight. Twelve days after the injection the abdomen was quite flat and only a small lump could be felt above the pubis. We should have liked to give her a further injection, but in view of the very serious symptoms which developed after the first it was considered necessary to delay treatment for a considerable time, and during the latter part of this period the lump increased in size. She has had further treatment, and although a mass of moderate size is still palpable, yet she looks and feels well, and is able to go about in the ordinary way.

CASE 185.—The patient was a young woman, 20 years of age, who herself discovered a lump in the abdomen. She came under our observation in March, 1925, when a laparotomy was done. A large retroperitoneal sarcoma was found, which was too vascular to be incised; a lymph gland was removed for diagnostic purposes. This was subsequently reported by Prof. Glynn to be sarcoma. Since that date she has had 0·05 g. of lead. Her general condition is very good. The lump is considerably smaller and is causing no symptoms.

CASE 177.—A woman, aged 52 years, was referred to us in November, 1924. She had some glycosuria, considerable jaundice, and there was a lump in the right hypochondrium. A laparotomy was performed, and a large mass felt in the head of the pancreas, and an anastomosis was done between the gall-bladder and the duodenum. She was subsequently treated with intravenous injections of colloidal lead. The jaundice has disappeared, and the glycosuria is considerably improved, and with the exception of one or two febrile attacks (? cholangitis) her general health is now very good. Distressing toxic symptoms developed after the last injection. The patient has gained over half a stone in weight. A section recently obtained shows scattered groups of a few atrophic cancer cells embedded in fibrous tissue.

### *Cases Believed Cured and Treatment Stopped.*

There are 30 cases which come into this group—3 males and 27 females. In a majority they were treated with injections of colloidal lead only. Two of them were treated with X rays in addition. Twelve cases had partial operation—that is to say, a removal was attempted but a considerable amount of malignant tissue was still left behind, and the patient was subsequently treated with lead. The following three cases are examples of the type in which the operation was incomplete, and which were subsequently treated with lead, with a satisfactory result.

CASE 9C.—A woman, aged 31 years, with malignant disease of the rectum. The rectum was excised, and the sigmoid brought down to the anal orifice, but a large mass of growth was left in the pelvis. Section showed it to be a typical columnar-celled carcinoma. Subsequently she was given 0·265 g. of lead. She is now very well and has gained weight, and there is no evidence of malignant disease.

CASE 24C.—The patient was a woman aged 39 years. She had a large ulcer high up on the posterior wall of the stomach behind the pancreas, causing hour-glass contraction. Partial gastrectomy was done and gastro-enterostomy, but there was much infiltrated tissue left behind. Section showed it to be a typical spheroidal-celled cancer. She was given 0·385 g. of lead. This patient has done well; she has gained weight and her appetite is good. There is no sign of malignant disease.

CASE 51.—The patient was a woman, aged 44 years, who two and a half years previously had had a radical operation on the left breast for carcinoma. On admission the abdomen was very distended and a mass could be felt in the pelvis. At the operation malignant ovarian tumours on both sides were removed. There were malignant nodules in the neighbourhood of the cæcum and in the omentum, which were not removed. She was subsequently given 0·765 g. of lead. This was over two years ago; she is still quite well and has gained considerable weight. There is no sign of recurrence.

Of those treated with lead and X ray—

CASE 140 is a good example. The patient was a man, aged 34 years, with a large sarcoma of the scapula and a mass of glands in the axilla, one of which was removed for section and found to be a mixed-celled sarcoma. He was given 0·22 g. of lead and several X ray exposures to the scapula only. In three months the scapula was normal. Altogether he has had 0·24 g. of lead, the last injection being given over 18 months ago. He is quite well, and there is no abnormality whatever of the scapula. His general health is good and he is able to follow his employment.

The following are examples of cases treated with injections of colloidal lead only.

CASE 117.—A woman, aged 57 years, who 15 months previously had had a radical operation for a carcinoma of the right breast. Fourteen months later the supraclavicular glands were removed. She was sent to us on account of a mass above the clavicle and in the axilla. She was given 0·19 g. of lead. The lumps have disappeared. The last injection was given over two years ago and she is still well and there is no recurrence.

CASE 81.—This patient was a young woman, aged 27 years, who in November, 1922, was operated upon for intestinal obstruction. A growth in the small intestine was found, and a lateral anastomosis was performed, no attempt being made to remove the tumour. A section of the growth showed it to be a lympho-sarcoma. She received 0·14 g. of lead. Her general condition is very good and there is nothing abnormal in the abdomen.

CASE 110.—This patient was a woman, aged 50 years, with ascites and small nodules of adenocarcinoma in the liver and omentum. No primary growth was found. She had to be tapped each fortnight and an average of 15 pints of fluid was withdrawn on each occasion. Subsequently she received 0·315 g. of lead. For the last 20 months the patient has been and looks very well. There is no sign of recurrence or of free fluid in the abdomen, and she is able to do her own housework.

CASE 50R.—This patient was a married woman, 55 years of age. She complained of irregular vaginal hæmorrhage. On examination she was found to have three nodules of considerable size in the vagina and an enlarged uterus. Hysterectomy was performed and a portion of one of the vaginal nodules was removed for section. The growth in the uterus was found to be a columnar-celled carcinoma and the piece of tissue removed from one of the vaginal nodules also proved to be adenocarcinomatous. She was treated, and in all received 0·52 g. of lead up to November, 1925. The masses in the vagina disappeared and her general health is in every way satisfactory. It is now (February, 1926) 13 months since the treatment was commenced, and a section recently prepared from a piece of hard tissue on the site of one of the pre-existing nodules shows nothing but fibrous tissue.

CASE 1.—This patient was a young woman, 36 years of age, who was sent to us with a large fungating carcinoma of the left breast. It was attached to deeper structures and there was a mass of glands in the axilla. Any operation was considered impracticable, but a portion of the edge of the ulcer was removed for section and proved to be carcinoma. She received 0·32 g. of lead. The ulcer healed in a fortnight and the whole tumour disappeared within six weeks. Subsequently a piece of breast tissue was removed and histological examination showed fibrous tissue only. At present—nearly five years since the treatment ceased—the patient is quite well and on palpation the breast appears to be normal. During this period she has had two babies and has nursed them at this breast. She comes to see us periodically to report herself.

### DISCUSSION OF CASES TREATED AND THE TREATMENT ADOPTED.

Limitations of space do not permit us to do more than comment in a general way on the patients treated. If, in estimating the value of the treatment of malignant disease by lead we exclude, for reasons already given, the cases in Groups 1, 2, 3, 5, and 6, we are left with Groups 4, 7, 8, and 9, from which to draw our conclusions. In allotting to these groups cases suitable to them we have erred on the side of caution. An example of this may be given in order to demonstrate that we have attempted not to over-estimate our results.

CASE 129.—The patient, aged 68, came to us in an emaciated condition, having a few months previously had a gastrostomy performed subsequently to complete occlusion of the œsophagus by cancer. We have not a section of this case, but the Wassermann reaction was negative. He had been operated on by Mr. Thelwall Thomas and also seen by Mr. Somerville Hastings, both of whom had no doubt whatsoever of the nature of his disease, which was also demonstrated by X ray examination. It is well known that few patients have ever lived more than nine months after gastrostomy in these circumstances and even this period is rarely covered. It is now two and a half years since the gastrostomy was performed in 1923, and the patient is in robust health and has put on several stones in weight. This man we should have been perfectly justified in putting either in Group 8 or 9. We have, however, preferred to put him in Group 7, as he has not been as conscientious as he should have been in continuing the treatment, which has now been stopped, having altogether had a little under 0·5 g. of lead.

We find in Group 4 a large number of patients who died of malignant disease in spite of a considerable amount of treatment. In these cases we may be said to have failed; yet the cause of failure may be attributed in many instances to the fact that the patient did not attend regularly for injections.

In many of the earlier cases failure was possibly due to our inexperience, which led us to give the metal in too small doses—a mistake only remedied in the last 18 months. Moreover, undoubtedly by slow poisoning in some of these early cases we reduced the general health of the patient, and rendered her less able to resist the disease. It must, however, be emphasised that in a large number the growth was considerably affected and altered by treatment, but by the time that stage had been reached it was impossible to continue treatment. Cases in Groups 7, 8, and 9 may be regarded as successes, although, as in all cases of supposed cure of cancer, time, and this time the rest of the life of the patient, alone can prove the truth of any statement on this matter. In at least four of our cases recorded as failures in Group 4 the growths disappeared completely, and the patients considered themselves cured. Treatment was stopped, but the condition recurred later.

As one of us has stated on a previous occasion,[3] X rays appear to exert an appreciably greater effect on a superficial tumour after treatment with lead. This is of great importance, as in suitable cases the assistance of X rays, after the patient has had as much lead as she can tolerate, may be a factor of moment in the treatment of the case.

With regard to operation followed by intravenous injections of lead, it has already been stated that, whenever possible, a very large tumour should be reduced in size, as the action of lead appears to be quantitative. When, however, a more or less radical operation, such as may be practised for a breast cancer with comparative ease and safety, is performed, the patient may be saved from a recurrence if injections of lead be given immediately after operation. Our results after vaginal hysterectomy, without the possibility of eradication, give evidence of the value of this procedure.

We recognise that those who commence the treatment of patients with lead will almost certainly be disappointed; for, indeed, they may have a series of failures before they obtain, if ever, a beneficial result. In any case, in spite of the fact that we have seen extraordinary happenings, they must not too confidently be expected. Moreover, we have never attempted to exclude operative and X ray treatment where these could be of assistance, and in every case we have only had in view the ultimate cure of a patient who generally had been abandoned to her fate.

It will be seen, therefore, that although we believe that lead is of great value in the treatment of malignant disease, either alone or in conjunction with other methods of treatment, we realise not only that it is but a substitute for something better, but also that the preparation made is far from perfect.

For all these reasons we would have preferred to work quietly on and to have kept the matter in our own hands until we felt reasonably certain that we could no further improve the method, and that the personal factor in regard to treatment was less important than it is to-day. We have no doubt whatever that, if lead were to come into the hands of all those who are clamouring for our preparation, the whole method would be condemned as useless.

## Comment by Dr. J. G. Adami.

I have followed with the deepest interest the developments in Prof. Blair Bell's method of treatment ever since he communicated to me its nature and showed me his first remarkable case of disappearance of an extensive and ulcerating carcinoma of the left breast. That was in the winter of 1920–21. The secondaries in the axilla had then disappeared: there was still a small area of induration to be felt in the outer part of the breast and the site of the old healed area of ulceration was still recognisable. Since then he has kept me fully advised as to each successive step. I have repeatedly seen his cases in the course of treatment, and I have been freely informed regarding the failures as well as the apparent successes, being a member of his first advisory committee and then becoming a member of the Executive of the Liverpool Cancer Research Committee established in February, 1923. The personnel of that Committee and of the large coöperative research Clinical Staff is given in Prof. Blair Bell's article in THE LANCET of Feb. 9th, 1924, p. 267.

On the mornings of July 15th, 16th, and 17th, 1925, as a medical member of that Executive I attended, with others, a review or survey of a number of old patients who had from the beginning been subjected to Prof. Blair Bell's treatment. Of these I saw and took notes of 30. Letters were read from 10 others all declaring themselves in good health, who for one cause or another could not respond to the call.

The main impressions left upon me by this very remarkable series of cases are the following.

1. The healthy, and indeed almost florid, appearance of the majority of the patients. There was complete absence of cachexia, absence also of any evidence of plumbic anæmia.

2. Absence of wrist-drop or other sign of lead poisoning; only one patient complained of some dimness of vision.

3. The rise in weight and good bodily condition of the majority, and, with this, their repeated testimony to the fact that they were now actively at work at their usual avocations.

4. The absence of evidence of recurrence. I had expected after this treatment, just as after X rays and radium, to be confronted with a fair proportion of recurrences within a year. There was not a single example in this group. The problem evidently resolves itself into this: What is the dose of lead which will surely kill off all the cancer cells without inflicting too grave an injury upon the other tissues of the body?

5. I could not but wonder whether it had been given to any other physician or surgeon to pass in review in three days 30 cases of recurrent and inoperable malignant growth, and to find one and all so actively going about their work in such apparently excellent health, with such absence of evidence of progressive disease. And this, even though there had been a mortality (in the main of those presenting themselves for treatment with the condition too far advanced) of more than 60 per cent. But then 60 per cent. or even 70 per cent. is a material reduction upon, say, 95 per cent.

I could not but be impressed with the fact that here we were dealing with an important step forward in the direction of ultimate control of what is one of the gravest ills which inflict mankind.

## Conclusions.

1. The results of treatment of malignant growths with preparations of lead add further testimony in support of our views of the nature of malignant neoplasia. These views have received confirmation, as shown in the previous papers, in all the directions that have been explored.

2. Much work remains to be done in regard to discovery of a more therapeutically active preparation of lead, which is at the same time less toxic generally.

3. All types of malignant growths are probably amenable to the beneficial influence of lead, provided the metal can reach the malignant cells in sufficient quantity.

4. Adjuvant surgical and radiological measures in suitable circumstances may be employed with considerable advantage. When the growth has been partly, or apparently entirely, removed, intravenous injections of lead should be employed within a few days of the operation when possible.

5. The method of treatment is difficult, and to some extent dangerous, and can only be safely employed by those who are thoroughly experienced in the work, and have laboratory facilities at their disposal.

We cannot conclude this series of contributions without expressing the deep sense of gratitude with which the whole staff, both clinical and experimental, of the Liverpool Cancer Research Committee, regard the interest and generosity of the following gentlemen who have not only made themselves responsible for the conduct of the work, but have also extended to us the sympathy which is so necessary in dealing with problems as difficult as that of cancer: Dr. J. G. Adami, Mr. Rex D. Cohen (treasurer), Mr. A. B. Earle, Sir Robert Jones, Mr. C. Sydney Jones, Mr. F. C. Minoprio, Mr. F. T. Paul, Sir James Reynolds, Colonel J. J. Shute, Mr. J. A. Smith (chairman), Mr. W. C. Stapleton, and Mr. R. Wilson. We wish also to thank Mr. E. Carey, the secretary, Miss Barnes and Miss Denby, assistant secretaries to the Cancer Research Committee, and the laboratory assistants, especially Mr. Manby and Mr. Sephton, for their ungrudging assistance.

# SOME RECENT WORK ON THE FUNCTIONS OF THE SPLEEN.

*A Lecture given to the Leeds University Medical Society on March 9th, 1926,*

BY JOSEPH BARCROFT, C.B.E., F.R.S.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF CAMBRIDGE.

ABOUT 15 months ago, in an address delivered in Manchester on Some Aspects of the Activity of the Spleen,[1] I put forward in a preliminary way a view of the splenic function which was at once old and new. New because it did not figure at all in the then current literature and thought, old because it can be stated in words published by Henry Gray in 1854.[2] These words are as follows:—

> "The function of the spleen is to regulate the quantity and the quality of the blood . . . the most satisfactory proof that we can possess is that the spleen really does contain, under certain circumstances, a varying amount of blood and that that amount is to such an extent as to justify us in concluding that the organ serves to regulate its quantity."

Probably I shall be expected to take up the story where I then dropped it and to state shortly what 15 months of work have added to the knowledge which we had at the commencement of 1925.

### *Comparative Size of the Spleen under Varying Conditions and After Death.*

The point of interest at that time was to arrive at some sort of judgment as to whether the spleen as it existed in the intact and normal animal was comparable in size to that seen in the same animal post mortem. The reason for this inquiry was as follows. There seemed good ground for the supposition that the spleen contracted, expelling red corpuscles from the spleen pulp into the general circulation under conditions of bodily stress, but the spleen seemed to be so small as to make this phenomenon one which was so trivial as to be of little importance. It seemed to be, if I might so say, rather a "property" than a "function" of the organ. A couple of experiments had sufficed, however, to show that under certain conditions the spleen at death was only about one-third *or one-quarter the size of the spleen during life.* Clearly a number of questions were raised by this observation: (1) How far were the conditions special to the two experiments performed, or how far were they general? (2) Granting that the shrinkage was due to the expulsion of blood constituents into the general circulation, what were these blood constituents? For instance, was the material expelled simply blood? or (3) Was there a preponderance of either corpuscles or plasma? (4) Were the corpuscles normal red blood corpuscles, or were they in any way distinguishable from those in the general circulation?

To these questions let me address myself.

1. The first condition in the experiments quoted, if it may be called a condition, was that they were both made upon cats. Is the phenomenon confined to cats or is it common to the higher animals generally? By the same methods which were used on the cat experiments have been performed on the dog and on the monkey, as well as many more on the cat. That on the dog produced an even more striking result than those on the cat. On the dog, as on the cat, the shrinkage caused both by hæmorrhage and by exercise was studied, with the following results, so far as hæmorrhage is concerned.

*Successive Bleedings.*

(A) = Total quantity of blood lost by dog.
(B) = Total quantity of blood lost by spleen.

| | (1) | (2) | (3) | (4) | (5) | (6) |
|---|---|---|---|---|---|---|
| (A) .. .. | 20 .. | 40 .. | 68 .. | 133 .. | 200 .. | 230 c.cm. |
| (B) .. .. | 5 .. | 25 .. | 39 .. | 44 .. | 50 .. | 52 c.cm. |

The experiments upon the monkey went in the opposite direction, and the method which we used *showed only a trifling change in the size of the spleen.* These experiments also revealed a weakness in the experimental method. The spleen of the monkey is—or perhaps I should say the spleens of our two monkeys were—roughly, quadrilateral pyramids, each face of which was an equilateral triangle. We put metal clips at three of the four angles, the fourth being the hilus, and proceeded to take X ray photos of the spleen when the animal had recovered from the operation. We then judged the size of the spleen from the position of the clips. Now it is clear that the spleen might expand in such a way as to turn the tetrahedron into a sphere without changing the positions of the clips. Such a change would increase the volume of the spleen about eight-fold.

These considerations indicate a weakness in the method which we employed. Partly on that account and partly because of the desire actually to see and not merely to deduce the effects which one describes, it seemed desirable to supplement the radiographic method of mensuration with a technique by which the spleen actually became visible. Mr. J. G. Stephens and I therefore have carried out a series of experiments in which the spleen was observed through a celluloid window. The first occasion on which we made any observations was on a cat in whose side a window had been placed by Dr. Florey and Mr. Stephens for another purpose. After a few preliminary experiments we decided so to perform the operation that the spleen was withdrawn from the abdomen. We therefore cut away as much of the skin and superior oblique muscle as was necessary for the window and made a slit in the inferior oblique and the parts of the body wall underneath it. Then we drew the spleen through the slit, sewed the cut edges of the inferior oblique loosely together underneath the spleen, so that the organ could not get back into the abdomen, and then put in the window. The wound healed up, enclosing the abdomen. Such an animal might probably be kept alive indefinitely, but we have not allowed any to live more than a fortnight. The spleen soon became obscure owing to the formation of a fibrous covering over it. In the latest experiments we have made a window which will open and allow of the spleen being cleaned.

*With such a preparation it is easy not only to* delineate the boundaries of the spleen, but to judge of the degree to which it is inflated, and in this latter respect it has yielded instructive results. The spleen of the dead cat is an organ the surfaces of which are, broadly speaking, flat, but in detail rough, and the edges of which are notched. The surfaces of the spleen in the resting live cat is quite different in appearance. The organ resembles a somewhat compressed sausage, being more or less elliptical instead of triangular in section. The surface is quite smooth.

These experiments gave confirmation to the series which we carried out by the X ray technique on the contraction of the spleen during exercise and hæmorrhage and death.

Fig. 1 shows the relative size of the resting spleen with that of the same organ after the cat had taken a trifling amount of exercise in a treadmill. The spleen apparently shrank to about two-thirds its superficial area, which would mean about one-half its volume. Moreover, the even sausage-shape contour is replaced by a much more angular one.

Fig. 2 shows a comparison between the living and the dead spleen. The white portion represents a piece of paper whose area is that of the spleen as marked off on the celluloid window when the cat was at rest; after death (by bleeding) the actual spleen was taken out and photographed on the white paper. In this case the volume of the dead spleen is about one-third that of the living organ when the animal was at rest.

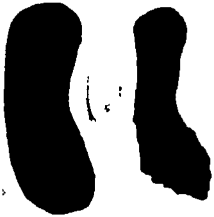
### *Study of the Blood which leaves the Spleen.*

2. In order to acquire a knowledge of the nature of the material which leaves the spleen researchers have for many years studied the composition of the blood in the splenic vein. They have obtained variable and, for the most part, negative results, finding little or no difference between the blood in the splenic vein and that in the general circulation. Looking back on such researches in the light of present knowledge they appear to be little short of tragic. Almost as well might one judge of the native Egyptian, or better, the temporary resident in Cairo, by making a careful study of the passenger on the mail steamers leaving the Suez Canal. These passengers come from almost everywhere but Egypt. Since an animal can breathe carbon monoxide for two hours without any of that gas appearing in the hæmoglobin of the spleen pulp, it follows that the blood which emerges from the splenic vein during all that time is short-circuited in some way and that it comes through a by-pass of some kind.

FIG. 1.

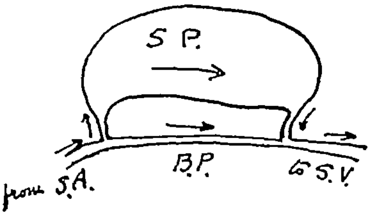


Rest. Exercise.

The physiological facts could be explained if the blood could choose alternative routes through the spleen, such as indicated by the following scheme. Precisely how such a representation, which is purely a sort of shorthand intended to represent the functional possibilities of travel, fits in with the anatomical details I am not prepared to discuss.

To obtain the blood from the spleen pulp in as pure a state as possible it is necessary to clamp the splenic artery (S.A.), then to stimulate the splenic nerve which will cause the blood to be expelled from the spleen pulp (S.P.) along the splenic vein (S.V.). When the splenic nerve is stimulated its action is found to be a very slow one, some eight minutes being necessary in the cat for the expulsion of as much material as will come. It does not come, however, at a uniform rate. In all as much as 13 c.cm. of material have been expelled from a spleen which at the end weighed about 6 g.

FIG. 3.

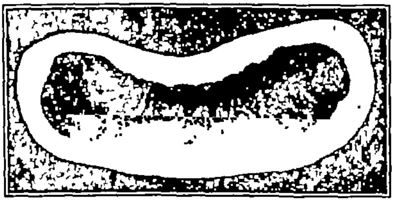


S.A. = splenic artery; S.V. = splenic vein; B.P. = by-pass; S.P. = spleen pulp. (The above is purely schematic and makes no assumption about the nature of the wall which encloses the spleen pulp.)

### *Increased Erythrocyte Count and Hæmoglobin Value of Blood Leaving Spleen.*

3. When the material emerging from the spleen pulp under such conditions is examined it clearly differs very much from the blood of the general circulation. The most apparent difference is to be found *in the relative number of erythrocytes found as* compared with that in the general circulation. If the spleen blood be collected[3] in successive samples, each of 1 c.cm., and these examined separately, it is found that the corpuscle count varies from cubic centimetre to cubic centimetre and reaching a maximum in the second or third cubic centimetre expelled. The same is true of the hæmoglobin value, which has been studied more particularly. At its maximum the hæmoglobin value would appear to be about 140 per cent. of that in the general circulation and on the average about 115 per cent. It will be seen that 13·6 c.cm. of material squeezed from the spleen pulp would correspond to approximately 15·6 c.cm. of blood.

FIG. 2.

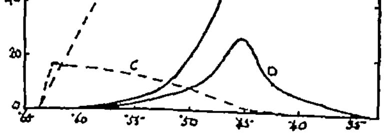


Shows a comparison between the living and dead spleen of a cat.

### *Increased Fragility of Corpuscles in Blood leaving Spleen.*

4. We now pass to the question, Are the corpuscles in the material expelled from the spleen pulp the same as those in the general circulation. Histological examination does not reveal any difference. No immature forms have been observed. Fragility tests, however, carried out by Orahovats[4] revealed some intensely interesting facts.

FIG. 4.



A = Per cent. corpuscles from spleen pulp laked } Against strength of salt solution
B = " " general circulation }

C = " " spleen pulp } Against increments of 0·05 per cent. salt solution.
D = " " general circulation }

Fig. 4, curves A and B respectively, show the fragility of the blood from the spleen pulp and the general circulation in a certain experiment. I should like to make it clear that this was the one which gave the most marked difference. Six consecutive experiments, however, all gave the same type of result. On the average the difference was about two-thirds that shown in the experiment here quoted, and it was about one-quarter to one-third that of the above in the experiment which gave the least conspicuous difference. In all cases, therefore, the difference was quite well marked. We were led to go into the question of fragility by a perusal of the work of Pearce, Krumbhaar, and Frazier on the spleen. Orahovats confirmed their principal results upon the effect of splenectomy on fragility. We would commend to the reader Dr. Krumbhaar's paper in the current number of *Physiological Reviews*.

---

[3] Cruickshank. Communicated to Physiological Society, December, 1925. See forthcoming number of Journal of Physiology.

[4] Communicated to Physiological Society, December, 1925. See forthcoming number of Journal of Physiology.

It had already been shown that not all the corpuscles in ordinary blood are of the same degree of fragility when exposed to hypotonic salt solutions. Brinkman[5] has classified them into three categories, which I shall call Class I., Class II., and Class III. The majority, Class II., the fragility of which differs but slightly from the fragility of the average and two smaller classes, I. and III., each of which contains a relatively small proportion of the corpuscles, but which covers a considerable range of fragility, I. being less fragile and III. more fragile than the average. Fig. 4, curve B, shows the percentage of corpuscles taken plotted against the strength of the salt solution and a glance at it will show the corpuscles of which Bruckmann's three classes are composed. On the particular blood shown Class I. would correspond approximately to corpuscles unlaked by 0·42 per cent. salt solution and would be about 10 per cent. of the whole, Class III. to corpuscles laked by salt solutions of greater strength than 0·52 per cent., and would also correspond to about 10 per cent. The remaining 80 per cent. would be in Class II.

It does not seem that Brinkman's classification amounts to more than that the fragility of the corpuscles has the sort of dispersion relative to the tonicity of the salt solution required to produce laking that most similar phenomena possess (see curve D); nevertheless, as Brinkman's classification is convenient we will retain it. The result of Orahovat's sex experiments in Brinkmann's language was as follows. The corpuscles in Class I. were uniformly more fragile in blood from the spleen pulp than from the general circulation. Similarly the corpuscles in Class B from the spleen pulp were uniformly more fragile than the same class in the circulating blood, whilst Class C did not exist in the blood from the spleen pulp. The impression given is that there is a limiting degree of fragility which cannot be exceeded, from whichever source the blood comes, but that whereas the corpuscles from the spleen pulp are very near that limit the majority of those from the general circulation enjoy a considerable margin of safety.

If instead of using hypotonic salt solution as a hæmolytic agent we have recourse to saponin we find that the corpuscles from the spleen pulp lake less easily than those from the general circulation. The phenomenon of corpuscles, which are abnormally fragile to hypotonic solutions and abnormally strong—if that is the opposite of fragile—to saponin, is no new one. It has been the subject of investigation by Rywosch,[6] who attributes it to insufficiency of phosphorous within the corpuscles. Here, then, appears to be a definite phenomenon, not only is the fluid in the spleen pulp somewhat richer in corpuscles than that in the general circulation, but the corpuscles are, on the whole, different, and this difference appears to be associated with a definite chemical deficiency.

It is too early to make any statement as to the physiological importance of the difference—i.e., as whether it is of advantage to the body that corpuscles of a certain character should be stored outside the general circulation and retained there in reserve. Corpuscles with these particular properties are reputed to be the oldest, but the demonstration does not appear to be convincing, and we are inquiring further as to whether it is the fact.

### *Explanations of Increased Fragility.*

Some observations may, however, be made on the mechanism by which the spleen acquires this accession of corpuscles of Class III. At first sight two obvious explanations present themselves: (1) The first is that the fragility (to hypotonic solutions and the word will be used in this sense in the remainder of the lecture) of the corpuscles is increased during their residence in the spleen pulp. (2) The second is that the corpuscles which on the whole are the most fragile are caught in the spleen pulp, which would therefore act as a sort of differential filter.

The first of these views seems, in the form in which it is stated, to run counter to the testimony both of theory and experiment. From the theoretical standpoint one may transcribe the curve given in Fig. 4, B, into the form shown in Fig. 4, D, plotting the percentage of corpuscles laked between consecutive concentrations of 0·05 per cent. salt solution against the actual concentrations. If a uniform reduction in the fragility of each corpuscle took place, by some reagent in the pulp acting upon all, a mere shifting of the curve would take place; and even if one supposed that the reagent acted unequally but in a regular manner, one would get a shifting coupled with a stretching or a general contraction, but neither of these is a true picture of what occurs.

The actual alteration is from Fig. 4, D, to C. This is more nearly what might occur if coupled with the progressive diminution in fragility; all corpuscles more fragile than those laked in 0·64 per cent. salt solution cease to exist. The figure is not unlike one which might be obtained if curve D were stretched out laterally and then the more fragile half of the curve cut off. Such a curve would mean a very large destruction of corpuscles, for if the spleen pulp contained 10 c.cm. of corpuscles the inference would be that 10 c.cm. or something of that order would be destroyed. While therefore this theory is attractive at first, it seems to make too great a demand on the corpuscles.

Let us pass to the second alternative, that the spleen is a filter. Such a curve as C would not be developed from D by the mere process of filtering off all corpuscles of more than a certain degree of fragility, but such a curve as C could be reproduced if one assumed that the prospect of a corpuscle being filtered off increased very rapidly with its fragility. Of course, it is not suggested that mere fragility would make the corpuscles more retentive by the spleen pulp; it is possible that fragility might go hand in hand with some other property, such as want of lability, or stickiness, which would have that effect.

On the experimental side Orahovats made an effort to decide between the rival claims of "increased fragility and bursting" and "differential filtration" along the following lines. It might be supposed that if the corpuscles were rendered more fragile and finally destroyed in the spleen pulp, that the process would extend over some time, and that the longer the corpuscles had resided in the spleen pulp the greater would be their fragility. On the other hand, if the process was one of mere filtration the corpuscles in the spleen pulp would differ as greatly from those in the general circulation at the moment of their arrival as after a long interval of time. Orahovats could not find that the time during which the corpuscles were held in the spleen pulp made any difference to their fragility. The spleen, if emptied by stimulation of the splenic nerve, takes several minutes to dilate and engorge itself once more, but at the end of this time the corpuscles within it are as fragile as they are after some hours' residence there, the spleen having been immobilised by section of the nerve. If, therefore, the corpuscles are reduced in fragility to the point of disintegration by some reagent in the spleen the effect must be completed very rapidly.

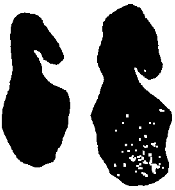
### *Mechanism of Dilatation of the Spleen.*

The work which has been discussed so far has centred largely about the contraction of the spleen. The subject of dilatation has only just commenced to engage our attention. The mechanism by which extensive dilatation is brought about is rather obscure. It is worth remembering that the spleen with its sinuses appears to be particularly susceptible of distension by the pressure of blood within it. Working against this pressure there are (1) resilience of elastic fibres in the spleen, and (2) the tone of the muscle

Clearly, in dilatation of the spleen there is, or may be, a nervous factor, and one may inquire from this point of view whether the musculature of the spleen possesses any properties different from those of the musculature of the splenic artery, or whether it may be regarded simply as an expansion of the tunica media of that vessel. One may inquire whether the spleen participates in the same reflexes on the arteries in the viscera. The older works on the subject describe the spleen as contracting on stimulation of the central end of the vagus. Accepting this statement, it seemed desirable to dissect out the bundle which contains the depressor fibres in the cat and stimulate it. If the result was constriction of the spleen it would be clear that the splenic musculature reacted differently from that of the visceral arterioles Dr. Masuda, who undertook this work, found quite the opposite result—namely, that the spleen dilated on stimulation of the depressor trunk of the cat vagus. Whilst the depressor dilatation of the spleen failed to bring out anything specific about its neuro muscular mechanism as compared with that of the vessels, it raised some very interesting points Of these the first for consideration is the appearance of the spleen in a mechanism which seems to be connected with the hydrostatic properties of the blood rather than with its function as an oxygen carrier. The function of the depressor presumably is to relieve the heart. It is wholly reasonable that the spleen should assist in that function by dilating, but the discovery that it does so shows that the nervous influences which govern its contraction are not confined to those which are initiated by want of oxygen in the central nervous system. The precise effect of stimulation of the depressor on the blood flow through the spinal cord is not known, but on general grounds one expects some degree of anoxæmia as a result of the fall in arterial pressure Yet the spleen, so far from contracting as it does in other instances of anoxæmia in the C.N.S., dilates.

It is possible to confront the body with circumstances calculated simultaneously to reduce the oxygen supply to the central nervous system and increase the burden thrown upon the heart. Such is the injection of a large quantity of normal saline. Will the response be constriction caused by the anæmia of the central nervous system or dilatation occasioned by the accession of a considerable volume of fluid to the circulation and the consequent burden upon the heart? The answer to this question is given in Fig. 5. Areas were obtained by Mr Stephens and myself by the celluloid window technique; frequent small injections of saline were made, 140 c.cm. being injected over an hour. The figure shows the area of the spleen as projected on the window, and it is only necessary to add that in addition to the evident increase in the surface of window occupied by the spleen, the organ presented a very tense appearance. There is no doubt that its volume was at least doubled.

FIG 5.



Before After
injection of saline

The experiment which I have just described is one of great interest also because it links the observations which have been made within the last two years with the dilatation of the spleen associated with anæmia; about that we are not yet in a position to speak. It must be reserved for some future occasion.

# Clinical and Laboratory Notes.

## NOTE ON THE
## TOXICITY OF CARBON TETRACHLORIDE
### *IN THE TREATMENT OF ANKYLOSTOMIASIS.*

BY M KHALIL, M.D BRUX., PH.D., M.R C.P. LOND.,
PROFESSOR OF PARASITOLOGY, FACULTY OF MEDICINE, CAIRO.

*(From the Parasitology Section, Public Health Laboratories, Cairo.)*

Carbon tetrachloride has been used on a large scale during the last three years as an anthelmintic in ankylostomiasis. The drug was generally considered as non-toxic, but some observers recorded toxic symptoms developing after its use in a very low percentage of the cases treated. The toxic symptoms varied in severity from transient attacks of dizziness, headache, and nausea to severe symptoms, such as vomiting, convulsions, and even death. Lambert,[1] in a series of 50,000 cases treated in Fiji, recorded three deaths, which he ascribed to impurities in the carbon tetrachloride used. Two other fatal cases were reported by Phelps and Hu.[2]

In Egypt carbon tetrachloride has been used on a large scale since 1923. The drug was supplied by a well-known British firm. In order to avoid any accidents, samples from every consignment of the drug were given to experimental animals in fairly big doses to detect any poisonous effect. The drug was also subjected to chemical analysis. The first consignment proved satisfactory. 20 c cm. given to a three-kilo monkey by a stomach-tube produced no ill-effects besides a transient diarrhœa. A ten-kilo dog was given as much as 100 c.cm. without developing any serious symptoms. The animal was perfectly normal in three days' time. This consignment of the drug was used in the Government anthelmintic hospitals with gratifying results. A second consignment of the drug from the same firm was tried on animals in the same way. 20 c.cm. were administered to a three-kilo monkey on Dec. 27th, 1923. The animal vomited once after two hours and abstained from taking food. It had no diarrhœa and died the following day. Post-mortem examination revealed the following morbid changes. Petechial hæmorrhage in the stomach wall, the terminal 15 cm. of the ileum were full of blood-stained slimy mucus; the intestinal wall was severely congested, and the contents contained carbon tetrachloride unmixed with the gut contents, other organs were practically normal. Another monkey was given 10 c.cm. of the same sample. It suffered from vomiting and diarrhœa, abstained from taking food, but ultimately recovered.

In view of these results the samples were chemically examined but no foreign ingredients were detected. Two litres of the drug were distilled and the residue of 5 c.cm. were given to a monkey by a stomach-tube, but no untoward symptoms developed. The first portion distilling over had a peculiar smell other than that of carbon tetrachloride and suggesting the presence of carbon bisulphide. 3.5 c cm of this were given to a monkey which died within 24 hours. The post-mortem revealed the presence of petechial hæmorrhages in the stomach wall. The last portion of the ileum was severely congested with blood-stained contents. No free carbon tetrachloride was found. Carbon tetrachloride distilling over after a first portion of 10 c.cm. was given to experimental animals, monkeys and dogs, but no bad symptoms appeared.

The question was consequently referred to Dr. H. H. Dale[3] and the British Medical Research Council. Dr. Dale communicated with the suppliers, who undertook to fractionate a large volume of the carbon tetrachloride, commercially known as "pure," and submitted the earliest distilling portion for examination by Dr. Harold King. Dr. King found that the small amount of sulphur present in the original sample was accumulated in this fraction, thus confirming the original observations made in Egypt. He, however, reported that it was all in the form of carbon bisulphide. The suppliers were advised to purify the drug from any traces of sulphur compounds.

Subsequent experiments in Egypt tended to show that the toxicity could not be ascribed to $CS_2$. Carbon bisulphide in varying amounts from 1–5 c.cm. were added to one dose of pure carbon tetrachloride and administered to experimental animals, including monkeys, without any ill-effects. On the other hand, the first fraction of a distillate of sulphur-free carbon tetrachloride proved non-toxic. It is therefore probable that the toxicity of ordinary so-called pure carbon tetrachloride is due to sulphur compounds other than carbon bisulphide, although the presence of the latter may be taken as an indication of the unsuitability of the drug for the treatment of ankylostomiasis. The actual toxic compounds remain to be identified.

Sulphur-free carbon tetrachloride can be used safely in doses of 5 c.cm. for the adult. This dose was found to be the most efficacious in expelling *Ankylostoma duodenale* in Egypt. During 1924 no less than 80,000 patients were treated by that drug at the Government anthelmintic hospitals without any fatalities. During the first nine months of 1925 no less than 56,392 patients were treated with only one fatal case. The patient was an old man of 60 years of age, addicted to the use of opium and alcohol. He suffered from collapse three hours after administration of 5 c.cm. of carbon tetrachloride and died within 24 hours. The post-mortem revealed hæmorrhagic embolic foci in the liver and heart.

### *Conclusions.*

(1) Some samples of so-called pure carbon tetrachloride are toxic to experimental animals and probably to man. (2) The toxic impurities are probably sulphur compounds distilling at a lower temperature than carbon tetrachloride (less than 76° C.). (3) The toxicity increases on keeping. (4) The toxic impurities can be got rid of by fractionating the carbon tetrachloride and throwing away the first portion of the distillate (about 1 per cent. of the total quantity). (5) The most effective dose in *Ankylostoma duodenale* infection is 5 c.cm., and this is perfectly safe if the purified drug is used.

The chemical work recorded in this paper was done by Mr. E. Griffiths-Jones, chief chemist of the Public Health Laboratories, to whom I am greatly indebted.

# NOTE ON THE OPERATIVE TREATMENT OF CARBUNCLE.

By Arthur Edmunds, C.B.,
M.S. Lond., F.R.C.S. Eng.,
SURGEON TO KING'S COLLEGE HOSPITAL.

Apart from scraping out with a sharp spoon, an instrument which I like to use as little as possible, the operative treatment of carbuncle resolves itself into making crucial or other incisions into it, or complete excision of the whole affected area. The following method has, I think, some advantages. In Fig. 1 the suggested incision is shown—namely, a crucial incision marking out four flaps which are dissected up as in Fig. 2. At the same time any necrotic area of the skin is cut away so that the flaps become rather ragged. Having reflected the flaps the whole of the suppurating area is cut away with the knife, and the resulting cavity packed with cyanide gauze wrung out in 1 in 40 carbolic, the flaps being turned outwards (Fig. 3). In this way the whole area is opened up to the maximum extent, but with this advantage, four flaps of skin have been left—a little irregular and ragged perhaps—but capable of being replaced in a few days, leaving the position as shown in Fig. 4. The saving of this skin in no way hinders the drainage, while it accelerates healing very much and diminishes the size of the ultimate scar. It might be expected that these flaps would slough, but as a matter of fact they very rarely do.

# Medical Societies.

## MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society on March 8th, Sir HOLBURT WARING, the President, in the chair, a discussion on

### OBSCURE PYREXIA IN ADULTS

was opened by Sir THOMAS HORDER. Departing from the usual methods pursued in arriving at a diagnosis in an obscure case, he set out to construct a series of inquiries to be elaborated under their several headings.

1. The first thought in the mind of the examiner approaching such a case was to enumerate the general causes of a state of pyrexia in a patient who showed few or no physical signs or symptoms. So frequently was pyrexia of microbial origin that some said, when it occurred in the absence of certain experimental drugs, it was always microbial. These would not admit a nervous origin of pyrexia, and acute gout they would probably attribute to microbic toxæmia, perhaps also severe hæmorrhage. There were also other examples of pyrexia which were difficult of explanation on a microbic basis, such as that in active Graves's disease, or that following severe exercise, or that occurring on the ninth or tenth day after the injection of horse serum. At times metabolic defects led to pyrexia quite apart from microbial activity; so in like manner did the injection into the body of foreign proteins. Acute arthritic gout could be accompanied by a pyrexia closely resembling that of septic arthritis. The fever of severe hæmorrhage was important and raised the question whether it was the natural result of a loss of blood, or was the result of an infection to which the loss of blood might have been due. Somewhat akin to this kind was the fever occurring after a period of hæmolysis in Addisonian anæmia. Here the pyrexia might be the direct result of the hæmolysis; it might be an expression of the unknown cause of the disease, presumably microbic, or possibly due to a secondary pyogenic infection. Cases of nervous pyrexia were not satisfactorily dismissed by saying that the pyrexia was always due to some microbial poison in the presence of an unstable thermo-taxic mechanism. If these people were not more poisoned than the generality, the important matter was the neuropathic patient, not the poison, and treatment should be directed to the neurosis and not to a toxæmia. Instability of the thermo taxic mechanism was also caused by alcohol and by the morphia habit, and an unusually high temperature for which an ordinary explanation could not be found should cause one to think of those drugs. A similar instability of this mechanism was caused by pregnancy and the parturient state, and a long febrile illness left the patient in such a susceptible condition that small and trivial causes would cause the temperature to mount. It would cause the belief among Anglo-Indians returning to this country after having malaria that they had a return of the disease. It was important to take cognisance of the patient's state of health just prior to the onset of the fever Sometimes the presence of an epidemic in the neighbourhood was a great help in assigning a cause for the temperature, but a suggestion that the case might be one of typhoid or of influenza would perhaps be countered by the doctor with the statement that there was no epidemic of those diseases, and yet the case might be an atypical one of such a disease, and the patient might have acquired it at some other place and developed the symptoms at home. Chronic diseases in the patient were occasionally of much diagnostic importance, he referred to such a condition as nephritis, especially if trauma occurred. An interesting group of cases were those in which surgery had taken place in a septic area, more particularly in connexion with a septic, perhaps a gangrenous, appendix Here the main question was whether a septic process was still in operation. The right lower quadrant of the pelvis, the subphrenic area, and just above the diaphragm were danger regions. Mastoid operations also might be followed by pyrexia, and in this connexion three questions should be attempted to be solved (1) Is there still a local septic zone which has not yet sufficiently drained? (2) is it a sinus thrombosis? (3) are the meninges infected?

2 The second consideration was as to whether the cause of the pyrexia was exogenous or endogenous. In most acute pyrexial diseases it was an exogenous infection, but in most subacute and chronic pyrexias the cause was probably endogenous. Sometimes these latter were acute, such as in coliform infection of the urinary tract, in which there might be no focal symptoms or signs for two days. In the past such cases had often been attributed to influenza, but with the present better knowledge of that disease it was hoped the mistake would be less frequent. He believed that the cases of so-called cystitis complicating influenza were not influenza at all, but were a coliform infection of the urinary tract. *Staphylococcus aureus* infections might be very acute and yet endogenous, the patient might have long had a trivial infection of that organism, pustular acne, a boil, or a neglected carbuncle.

3 The third consideration concerned investigation as to the portal of entry. In many cases this was the respiratory tract, and after the first entry of the cause there was little about the portal remaining to incriminate it.

4 The fourth consideration, and one more prolific of results, was the avenue of spread of the infection, or the particular tissue or tract involved. This consideration resolved itself into passing in review systematically the various paths by which infecting agents got into the deeper tissues. The aim should be to prevent the mind becoming discursive; each path should be carefully examined, and one should never be afraid of a large number of negative examinations, because one was well repaid by striking a positive fact, which would not otherwise have emerged. Different microbes affected different tissues, therefore examination of the tissue systems seriatim would often reveal a lesion or functional defect which would suggest the nature of the organism concerned

5 With regard to the fifth consideration, there were deep-seated organs in which infective processes were apt to get "bedded in" once the infection had become established Several times he had been led to think the infective agent was staphylococcus—and it proved to be so—by considering such tissue as bone, which was notoriously silent as to signs and symptoms. Attention should be paid to the description of any pain by the patient, it was significant if he did not refer it to a particular spot. In osteomyelitis the pyrexia was of the obscure kind for some weeks. A very important deep organ was the liver; there might be a patch of perihepatitis with an infection of the liver below And in the perinephric tissues the *S aureus* might cause pyrexia without symptoms for days, perhaps weeks, but an earlier diagnosis could be made by remembering that it might have started as a blood infection, and that this would cause an intermitting fever Another "cryptic" region for infection was the subphrenic. And he had been impressed again and again with the latency of pleurisy. Too much importance was usually attached to the pleuritic rub There might be a long course of pleurisy without physical signs, moreover, the pain of that disease might be referred to the top of the shoulder, the front of the chest, the region of the vertebræ, or over the crest of the ileum.

Twice, said Sir Thomas Horder, he had seen aneurysm associated with obscure pyrexia, and he thought it was pleurisy in association with the aneurysm which led to the pyrexia. Other cryptic areas of trouble causing pyrexia were the sinuses of the nose, and the sphenoidal sinus seemed to be the chief culprit in this region. A further consideration concerned the nature of the organism. Probably the tubercle bacillus headed the list of organisms which caused obscure temperature. Strept

had their distinguishing characters; they were liable to occur in bone, perinephric tissues, liver. Also spirochætal infections other than those of syphilis must also be remembered, and an acute fever might be associated with coliform infections.

Still another consideration was the form of the temperature chart; sometimes the help derived from this was so great as to be practically diagnostic. The charts should be studied systematically, and not only four-hourly, but over a long period, for then a character might be revealed which was not evident over the shorter periods. Finally, he referred to clinico-pathological helps in diagnosis. It was useful, he said, to make the clinical investigation of a case as thorough as possible before deciding on the pathological investigation to be pursued. It was not justifiable to have all the latter done, partly for economical reasons from the patient's point of view, but also because they were exhausting to an ill person. And pathological findings could only be properly interpreted in connexion with the clinical side. Diagnoses made in the laboratory were often quite brilliant, but also sometimes to be regretted. Sometimes, in these circumstances, a case was diagnosed as lymphatic leukæmia when it was really a mononucleosis. Clinical facts must always be regarded as positive data.

### *Discussion.*

Dr. C. E. LAKIN said that most of the cases of the kind under discussion were either instances of a common disease occurring in a disguised form, or were examples of rare or unusual diseases. His contribution consisted of relating cases in which the causation of the fever caused a good deal of difficulty. One was that of a middle-aged man who, when seen, had been ill four weeks. As it was thought to be typhoid a Widal reaction was done, but on this and other occasions it was negative. The man was indifferent to his surroundings, almost stuporose, and a surgeon suggested he had a frontal abscess. The temperature chart suggested typhoid. As the spleen was palpable a further Widal was done, but again with a negative result. In ten days the patient died, and the post-mortem revealed typical typhoid ulcers; the organisms were obtained from these ulcers and from the gall-bladder. A case of supposed apical pneumonia went from bad to worse and was of a puzzling nature, and post-mortem examination revealed extensive carcinoma of the bronchus on the right side. He narrated other interesting cases, and said he believed a number of cases of obscure pyrexia in the absence of symptoms were due to a small dose of infecting organisms.

Mr. ZACHARY COPE said that a puzzling condition to diagnose was an abscess in the middle of the lung, causing neither pain nor physical signs; he had known such cases diagnosed as neurasthenia. On one patient he was asked to operate for subphrenic abscess, as there was rigidity over one part of the diaphragm, but the leucocyte count was 250,000 per c.mm., and it was found to be a case of spleno-medullary leukæmia. Deep sarcoma could also cause a puzzling pyrexia.

Dr. H. A. DES VŒUX quoted an instance in which fever of several weeks' duration was found to be due to nothing more than a tape-worm; the temperature kept at 103° to 104°F. Syphilis was sometimes the cause of an obscure pyrexia, and also tuberculosis in an aged person.

Dr. HERBERT FRENCH discussed the question of blood agglutinations helping to decide whether a particular organism was the cause of the trouble in a case. Also whether blood culture methods had been so perfected as to make them valuable for diagnosis, and whether cultures from the urine enabled one to say what organisms were responsible for a prolonged pyrexia.

Dr. F. G. CHANDLER emphasised the importance of the leucocyte count in diagnosing these obscure conditions; leucocytosis enabled a differentiation to be at once made between subphrenic or perinephric abscess and tuberculosis or typhoid. He quoted cases

Dr. G. W. GOODHART said he did not think there should be such a thing as a laboratory diagnosis.

Dr. W. J. ADIE stated that prolonged fever might be due to encephalitis lethargica; the attack might be so mild as not to arouse the physician's suspicion; but the later development of the Parkinsonian syndrome confirmed its nature.

Mr. J. E. H. ROBERTS, Mr. E. B. WAGGETT, Dr. LENNOX WAINWRIGHT, Dr. PARKES WEBER, and Mr. H. TILLEY also related cases and the ultimate diagnoses.

The PRESIDENT said it would have been of enormous advantage if such a paper as Sir Thomas Horder's had been written and circulated among members of the R.A.M.C. in the early days of the war, remembering the many cases of "P.U.O." He strongly agreed with the opener's suggestion that in cases of obscure pyrexia the clinician should first make a very thorough examination. Many cases of pyrexia remained obscure as to their nature because the physician had not, in the first place, done his work in a proper way. Pathological investigations should follow the clinical in every case. He also agreed with paying attention to everything the patient had to say. In quite a number of cases the cause of pyrexia remained obscure until exploration was made of the gall-bladder region.

Sir THOMAS HORDER replied.

# ROYAL SOCIETY OF MEDICINE.

## COMBINED SECTIONS OF SURGERY, MEDICINE, ELECTRO-THERAPEUTICS, AND THERAPEUTICS.

### TREATMENT OF EXOPHTHALMIC GOITRE: IODINE THERAPY.

AT a combined meeting of these Sections held on March 3rd, Dr. GEORGE GRAHAM (Therapeutics) in the chair, Prof. E. MELLANBY reminded members that at the discussion of this subject by the Society in 1921 iodine was not even mentioned. This omission was not due to lack of knowledge that iodine had a profound influence on the disease, but was because many recognised that subjects of the disease could be harmed by iodine. But if the capacity of a therapeutic agent to cause harm was to be regarded as a cause for its rejection, the sooner all practitioners became homœopaths the better. Such valuable drugs as mercury, digitalis, ipecacuanha, &c., could do a great deal of harm. The need was to inquire into the conditions in which iodine could produce in the disease baneful effects. In exophthalmic goitre hyperplasia of the gland occurred, and this could easily be induced in dogs. He showed photographs of the thyroid glands of a litter of five dogs, all brought up on ordinary food. The thyroid glands of three were 44 times the size of the others, and the only difference in the diet was that in the case of the dogs with the large glands a little cod-liver oil was given with the food, and to the others was given the same weight of butter (cod-liver oil containing a small quantity of iodine). The small glands were shown to be full of colloid, while in the large ones a condition of real hyperplasia was found. Iodine, therefore, seemed to exercise a profound influence in regulating the size and structure of that gland. The dogs with hyperplasia of the gland had no symptoms of hyperthyroidism. In the latter condition the use of iodine in a few dogs made the heart beat more slowly, sweating was greatly reduced, and the tremors diminished and then disappeared, the state of the patient being changed from one of restlessness and semi-dementia to placidity and almost normality. He showed charts of the pulse-rate and the improvement brought about by giving iodine; the oxygen intake and the basal metabolism were both greatly reduced under the treatment. In one case a basal metabolism which had varied between + 33 and + 48 was brought down to normal on the eighth day by adding 1 gr. of iodine per day to the food. It was at this stage that operation was most favourable, Unfortunately, after this stage had been reached, the symptoms showed a tendency to reappear, even though the iodine treatment was continued and the food was restricted to 1800 calories per diem. Stoppage of the iodine brought about a real exacerbation of symptoms. However long the iodine was persisted with, there was a return of the unfavourable factors on its cessation. The iodine seemed to keep the intensity of the symptoms in check. In some cases the usual effect just described did not follow the giving of iodine. The first effect might give place to a sudden acute exacerbation of symptoms, the basal metabolism went up, and the patient became much worse Recovery occurred in a few days, and if the treatment were continued thereafter another exacerbation ensued. The cases in which this occurred were those of toxic adenomata, people who had had large thyroids and who then developed hard, knobby glands. Their acini were very distended and swollen owing to the contained colloid. Sometimes the thyroid got so large that it caused respiratory obstruction, rendering operation imperative, and not at a stage which the surgeon would choose for it.

Among the advantages of iodine therapy were that a rapid disappearance of the symptoms was brought about by giving iodine, and this proved a valuable aid to surgery The general condition of the patient was also greatly improved. Some cases completely recovered after this treatment; he had tested some over a period of four years. Many said that if cases of exophthalmic goitre were left alone they would recover spontaneously, and some evidence was available to that effect, while at the last discussion on the subject Sir William Hale-White supported the contention by statistics. The disadvantages were that in some cases, particularly in secondary Graves's disease or toxic adenoma, there were certain definite dangers of a sudden exacerbation of symptoms. This was so pronounced that he did not now give such people—with hard, knobby glands—iodine at all. A further disadvantage was that stoppage of the iodine caused an exacerbation of symptoms. Another was the danger of asphyxia due to the colloid filled gland causing pressure on vital structures. He gave the patients a good diet, but kept the total calories low, as in experimental animals it was found that the greater the quantity of food taken the bigger the gland became. On the whole, he considered iodine therapy was a valuable adjunct in the treatment of exophthalmic goitre.

Dr. J. W. McNEE said his interest was aroused in this aspect of the subject when Means, of Boston, U.S.A., showed, in 1924, the effects of giving Lugol's iodine in cases which were being prepared for operation on the thyroid gland. Within limitations this revival of the treatment of goitre must be classed as a very great improvement as a safe preparation for operation. From 10 to 12 days after commencing the iodine seemed to be the best time for operation, and it could be gauged chiefly by the pulse-rate, without metabolic determinations. He was sure that such a fall of pulse-rate and general improvement could not be brought about, as some contended, by rest in bed alone. Some improvement followed such rest, but on giving iodine it at once became more marked. By operating at the period of 10 or 12 days the general mortality had been definitely reduced, and surgeons could now operate on the gland with much greater safety and take away a larger part of it than they formerly cared to attempt. Since he took an interest in this subject he had noted the frequency with which symptoms returned after hemi-thyroidectomy had been carried out. In the last few months he had seen four cases—one operated on six years ago, one four years ago, and the others three years ago—in which great exacerbation of symptoms occurred; and all had now been re-operated on under the new conditions and all with complete success Even when, after ceasing iodine, there was a return of symptoms, these were never so severe as they had been originally.

With regard to the use of iodine in controlling the so-called crises in exophthalmic goitre, he had not seen in this country cases of anything like the severity of some he saw from the Mississippi Valley in America, the eyes of some of the patients lying out on their cheeks, accompanied by double pan-ophthalmitis, and the people being acutely insane. Still, he had seen in England severe cases with great mental disturbance, and the effect of iodine was to produce a profound and rapid improvement, sometimes within a few hours; 15 ♏ of Lugol's iodine produced great benefit in a day or two. The cardiac failure in Graves's disease—often, but not always, associated with auricular fibrillation—he did not agree was successfully treated by iodine, as alleged by Plummer. In one or two severe cases, with great œdema and ascites and effusions into the pleura, even large doses of iodine produced no effect at all. But when digitalis was substituted for the iodine a good effect was at once obtained. He had tried, in the out-patient department, giving iodine alone for a period of six months, but he had not been impressed with the result, and two he had brought into the ward to put them on to iodine treatment there, and they were subsequently operated upon.

With regard to the mechanism of exophthalmic goitre and how iodine was related to it, he was much interested in the work at Rochester in connexion with the possible presence in these thyroid glands of a substance differing from thyroxin. That work had not yet been published, but it seemed one of the likeliest explanations—namely, that in these cases there was a substance allied to thyroxin but differing from it, in which some of the iodine was replaced by some other compound.

Dr. GUSTAV MONOD (Vichy) referred to the case of a woman, aged 45, who was admitted to hospital with a very definite complex of Graves's disease. She was submitted to X rays, but with no result. She then developed glycosuria, and she was given large doses of insulin for this, while retaining the normal diet. As expected, the diabetic symptoms cleared up immediately, and there was also a rapid improvement in all the exophthalmic goitre symptoms. After a few months, however, the patient developed pneumonia and died. He had found that cases of exophthalmic goitre were very tolerant of insulin. He wondered whether, in supplying insulin to the body, one was bringing about the same result as by performing thyroidectomy.

Prof F R. FRASER said that at the hospital he was attached to 50 cases of exophthalmic goitre had been treated with iodine in the last five years. At the beginning of that period there was no guidance as to dosage, hence, in a certain number of cases, harm was done. Doses of 30 ♏ of the 10 per cent. solution in alcohol a day were used, increased, in some instances, to 60 ♏, and in one case to 180 ♏ per diem. When harm was done it took two forms. One was the production of symptoms of iodism; the other was to cause a great enlargement and hardening of the thyroid gland and an exacerbation of the tachycardia, the palpitations, and the sense of choking. It was later found that results as good followed the use of smaller doses, and gradually the present scale of dosage was evolved. Mainly they used a 10 per cent. solution of iodine in 95 per cent. alcohol. Still, any ionised form of iodine answered equally well. Some people prescribed tincture of iodine which contained a large proportion of iodine as well as iodide. The particular preparation intended should always be specified. At St Bartholomew's Hospital patients had been kept in bed and the severity of their symptoms of intoxication, their basal metabolic rates, &c., estimated, and then they were started on 5 ♏ of the alcohol solution three times a day. When the maximum result had been attained, the quantity was reduced to 10 ♏ a day, this being further reduced to 5 ♏ daily before the patient left the hospital, and this was the largest dose on which patients were allowed to leave the institution, otherwise severe exacerbations were liable to occur before they could be checked. He agreed that, however carefully watched, there were cases in which harm was done,

had their distinguishing characters; they were liable to occur in bone, perinephric tissues, liver. Also spirochætal infections other than those of syphilis must also be remembered, and an acute fever might be associated with coliform infections.

Still another consideration was the form of the temperature chart; sometimes the help derived from this was so great as to be practically diagnostic. The charts should be studied systematically, and not only four-hourly, but over a long period, for then a character might be revealed which was not evident over the shorter periods. Finally, he referred to clinico-pathological helps in diagnosis. It was useful, he said, to make the clinical investigation of a case as thorough as possible before deciding on the pathological investigation to be pursued. It was not justifiable to have all the latter done, partly for economical reasons from the patient's point of view, but also because they were exhausting to an ill person. And pathological findings could only be properly interpreted in connexion with the clinical side. Diagnoses made in the laboratory were often quite brilliant, but also sometimes to be regretted. Sometimes, in these circumstances, a case was diagnosed as lymphatic leukæmia when it was really a mononucleosis. Clinical facts must always be regarded as positive data.

### *Discussion.*

Dr. O. E. Lakin said that most of the cases of the kind under discussion were either instances of a common disease occurring in a disguised form, or were examples of rare or unusual diseases. His contribution consisted of relating cases in which the causation of the fever caused a good deal of difficulty. One was that of a middle-aged man who, when seen, had been ill four weeks. As it was thought to be typhoid a Widal reaction was done, but on this and other occasions it was negative. The man was indifferent to his surroundings, almost stuporose, and a surgeon suggested he had a frontal abscess. The temperature chart suggested typhoid. As the spleen was palpable a further Widal was done, but again with a negative result. In ten days the patient died, and the post-mortem revealed typical typhoid ulcers; the organisms were obtained from these ulcers and from the gall-bladder. A case of supposed apical pneumonia went from bad to worse and was of a puzzling nature, and post-mortem examination revealed extensive carcinoma of the bronchus on the right side. He narrated other interesting cases, and said he believed a number of cases of obscure pyrexia in the absence of symptoms were due to a small dose of infecting organisms.

Mr. Zachary Cope said that a puzzling condition to diagnose was an abscess in the middle of the lung, causing neither pain nor physical signs; he had known such cases diagnosed as neurasthenia. On one patient he was asked to operate for subphrenic abscess, as there was rigidity over one part of the diaphragm, but the leucocyte count was 250,000 per c.mm., and it was found to be a case of spleno-medullary leukæmia. Deep sarcoma could also cause a puzzling pyrexia.

Dr. H. A. Des Vœux quoted an instance in which fever of several weeks' duration was found to be due to nothing more than a tape-worm; the temperature kept at 103° to 104°F. Syphilis was sometimes the cause of an obscure pyrexia, and also tuberculosis in an aged person.

Dr. Herbert French discussed the question of blood agglutinations helping to decide whether a particular organism was the cause of the trouble in a case. Also whether blood culture methods had been so perfected as to make them valuable for diagnosis, and whether cultures from the urine enabled one to say what organisms were responsible for a prolonged pyrexia.

Dr. F. G. Chandler emphasised the importance of the leucocyte count in diagnosing these obscure conditions; leucocytosis enabled a differentiation to be at once made between subphrenic or perinephric abscess and tuberculosis or typhoid. He quoted cases in point.

Dr. G. W. Goodhart said he did not think there should be such a thing as a laboratory diagnosis.

Dr. W. J. Adie stated that prolonged fever might be due to encephalitis lethargica; the attack might be so mild as not to arouse the physician's suspicion; but the later development of the Parkinsonian syndrome confirmed its nature.

Mr. J. E. H. Roberts, Mr. E. B. Waggett, Dr. Lennox Wainwright, Dr. Parkes Weber, and Mr. H. Tilley also related cases and the ultimate diagnoses.

The President said it would have been of enormous advantage if such a paper as Sir Thomas Horder's had been written and circulated among members of the R.A.M.C. in the early days of the war, remembering the many cases of "P.U.O." He strongly agreed with the opener's suggestion that in cases of obscure pyrexia the clinician should first make a very thorough examination. Many cases of pyrexia remained obscure as to their nature because the physician had not, in the first place, done his work in a proper way. Pathological investigations should follow the clinical in every case. He also agreed with paying attention to everything the patient had to say. In quite a number of cases the cause of pyrexia remained obscure until exploration was made of the gall-bladder region.

Sir Thomas Horder replied.

#### Treatment of Exophthalmic Goitre: Iodine Therapy.

At a combined meeting of these Sections held on March 3rd, Dr. George Graham (Therapeutics) in the chair, Prof. E. Mellanby reminded members that at the discussion of this subject by the Society in 1921 iodine was not even mentioned. This omission was not due to lack of knowledge that iodine had a profound influence on the disease, but was because many recognised that subjects of the disease could be harmed by iodine. But if the capacity of a therapeutic agent to cause harm was to be regarded as a cause for its rejection, the sooner all practitioners became homœopaths the better. Such valuable drugs as mercury, digitalis, ipecacuanha, &c., could do a great deal of harm. The need was to inquire into the conditions in which iodine could produce in the disease baneful effects. In exophthalmic goitre *hyperplasia* of the gland occurred, and this could easily be induced in dogs. He showed photographs of the thyroid glands of a litter of five dogs, all brought up on ordinary food. The thyroid glands of three were 44 times the size of the others, and the only difference in the diet was that in the case of the dogs with the large glands a little cod-liver oil was given with the food, and to the others was given the same weight of butter (cod-liver oil containing a small quantity of iodine). The small glands were shown to be full of colloid, while in the large ones a condition of real hyperplasia was found. Iodine, therefore, seemed to exercise a profound influence in regulating the size and structure of that gland. The dogs with hyperplasia of the gland had no symptoms of hyperthyroidism. In the latter condition the use of iodine in a few dogs made the heart beat more slowly, sweating was greatly reduced, and the tremors diminished and then disappeared, the state of the patient being changed from one of restlessness and semi-dementia to placidity and almost normality. He showed charts of the pulse-rate and the improvement brought about by giving iodine; the oxygen intake and the basal metabolism were both greatly reduced under the treatment. In one case a basal metabolism which had varied between + 33 and + 18 was brought down to normal on the eighth day by adding 1 gr. of iodine per day to the food. It was at this stage that operation was most favourable, Unfortunately, after this stage had been reached, the symptoms showed a tendency to reappear, even though the iodine treatment was continued and the food was restricted to 1800 calories per diem. Stoppage of the iodine brought about a real exacerbation of symptoms. However long the iodine was persisted with, there was a return of the unfavourable factors on its cessation. The iodine seemed to keep the intensity of the symptoms in check. In some cases the usual effect just described did not follow the giving of iodine. The first effect might give place to a sudden acute exacerbation of symptoms, the basal metabolism went up, and the patient became much worse. Recovery occurred in a few days, and if the treatment were continued thereafter another exacerbation ensued. The cases in which this occurred were those of toxic adenomata, people who had had large thyroids and who then developed hard, knobby glands. Their acini were very distended and swollen owing to the contained colloid. Sometimes the thyroid got so large that it caused respiratory obstruction, rendering operation imperative, and not at a stage which the surgeon would choose for it.

Among the advantages of iodine therapy were that a rapid disappearance of the symptoms was brought about by giving iodine, and this proved a valuable aid to surgery. The general condition of the patient was also greatly improved. Some cases completely recovered after this treatment; he had tested some over a period of four years. Many said that if cases of exophthalmic goitre were left alone they would recover spontaneously, and some evidence was available to that effect, while at the last discussion on the subject Sir William Hale-White supported the contention by statistics. The disadvantages were that in some cases, particularly in secondary Graves's disease or toxic adenoma, there were certain definite dangers of a sudden exacerbation of symptoms. This was so pronounced that he did not now give such people—with hard, knobby glands—iodine at all. A further disadvantage was that stoppage of the iodine caused an exacerbation of symptoms. Another was the danger of asphyxia due to the colloid-filled gland causing pressure on vital structures. He gave the patients a good diet, but kept the total calories low, as in experimental animals it was found that the greater the quantity of food taken the bigger the gland became. On the whole, he considered iodine therapy was a valuable adjunct in the treatment of exophthalmic goitre.

Dr. J. W. McNee said his interest was aroused in this aspect of the subject when Means, of Boston, U.S.A., showed, in 1924, the effects of giving Lugol's iodine in cases which were being prepared for operation on the thyroid gland. Within limitations this revival of the treatment of goitre must be classed as a very great improvement as a safe preparation for operation. From 10 to 12 days after commencing the iodine seemed to be the best time for operation, and it could be gauged chiefly by the pulse-rate, without metabolic determinations. He was sure that such a fall of pulse-rate and general improvement could not be brought about, as some contended, by rest in bed alone. Some improvement followed such rest, but on giving iodine it at once became more marked. By operating at the period of 10 or 12 days the general mortality had been definitely reduced, and surgeons could now operate on the gland with much greater safety and take away a larger part of it than they formerly cared to attempt. Since he took an interest in this subject he had noted the frequency with which symptoms returned after hemi-thyroidectomy had been carried out. In the last few months he had seen four cases—one operated on six years ago, one four years ago, and the others three years ago—in which great exacerbation of symptoms occurred; and all had now been re-operated on under the new conditions and all with complete success. Even when, after ceasing iodine, there was a return of symptoms, these were never so severe as they had been originally.

With regard to the use of iodine in controlling the so-called crises in exophthalmic goitre, he had not seen in this country cases of anything like the severity of some he saw from the Mississippi Valley in America, the eyes of some of the patients lying out on their cheeks, accompanied by double pan-ophthalmitis, and the people being acutely insane. Still, he had seen in England severe cases with great mental disturbance, and the effect of iodine was to produce a profound and rapid improvement, sometimes within a few hours; 15 ♏ of Lugol's iodine produced great benefit in a day or two. The cardiac failure in Graves's disease—often, but not always, associated with auricular fibrillation—he did not agree was successfully treated by iodine, as alleged by Plummer. In one or two severe cases, with great œdema and ascites and effusions into the pleura, even large doses of iodine produced no effect at all. But when digitalis was substituted for the iodine a good effect was at once obtained. He had tried, in the out-patient department, giving iodine alone for a period of six months, but he had not been impressed with the result, and two he had brought into the ward to put them on to iodine treatment there, and they were subsequently operated upon.

With regard to the mechanism of exophthalmic goitre and how iodine was related to it, he was much interested in the work at Rochester in connexion with the possible presence in these thyroid glands of a substance differing from thyroxin. That work had not yet been published, but it seemed one of the likeliest explanations—namely, that in these cases there was a substance allied to thyroxin but differing from it, in which some of the iodine was replaced by some other compound.

Dr. Gustav Monod (Vichy) referred to the case of a woman, aged 45, who was admitted to hospital with a very definite complex of Graves's disease. She was submitted to X rays, but with no result. She then developed glycosuria, and she was given large doses of insulin for this, while retaining the normal diet. As expected, the diabetic symptoms cleared up immediately, and there was also a rapid improvement in all the exophthalmic goitre symptoms. After a few months, however, the patient developed pneumonia and died. He had found that cases of exophthalmic goitre were very tolerant of insulin. He wondered whether, in supplying insulin to the body, one was bringing about the same result as by performing thyroidectomy.

Prof. F. R. Fraser said that at the hospital he was attached to 50 cases of exophthalmic goitre had been treated with iodine in the last five years. At the beginning of that period there was no guidance as to dosage, hence, in a certain number of cases, harm was done. Doses of 30 ♏ of the 10 per cent. solution in alcohol a day were used, increased, in some instances, to 60 ♏, and in one case to 180 ♏ per diem. When harm was done it took two forms. One was the production of symptoms of iodism; the other was to cause a great enlargement and hardening of the thyroid gland and an exacerbation of the tachycardia, the palpitations, and the sense of choking. It was later found that results as good followed the use of smaller doses, and gradually the present scale of dosage was evolved. Mainly they used a 10 per cent. solution of iodine in 95 per cent. alcohol. Still, any ionised form of iodine answered equally well. Some people prescribed tincture of iodine which contained a large proportion of iodine as well as iodide. The particular preparation intended should always be specified. At St. Bartholomew's Hospital patients had been kept in bed and the severity of their symptoms of intoxication, their basal metabolic rates, &c., estimated, and then they were started on 5 ♏ of the alcohol solution three times a day. When the maximum result had been attained, the quantity was reduced to 10 ♏ a day, this being further reduced to 5 ♏ daily before the patient left the hospital, and this was the largest dose on which patients were allowed to leave the institution, otherwise severe exacerbations were liable to occur before they could be checked. He agreed that, however carefully watched, there were cases in which harm was done,

had their distinguishing characters; they were liable to occur in bone, perinephric tissues, liver. Also spirochætal infections other than those of syphilis must also be remembered, and an acute fever might be associated with coliform infections.

Still another consideration was the form of the temperature chart; sometimes the help derived from this was so great as to be practically diagnostic. The charts should be studied systematically, and not only four-hourly, but over a long period, for then a character might be revealed which was not evident over the shorter periods. Finally, he referred to clinico-pathological helps in diagnosis. It was useful, he said, to make the clinical investigation of a case as thorough as possible before deciding on the pathological investigation to be pursued. It was not justifiable to have all the latter done, partly for economical reasons from the patient's point of view, but also because they were exhausting to an ill person. And pathological findings could only be properly interpreted in connexion with the clinical side. Diagnoses made in the laboratory were often quite brilliant, but also sometimes to be regretted. Sometimes, in these circumstances, a case was diagnosed as lymphatic leukæmia when it was really a mononucleosis. Clinical facts must always be regarded as positive data.

### *Discussion.*

Dr. C. E. **Lakin** said that most of the cases of the kind under discussion were either instances of a common disease occurring in a disguised form, or were examples of rare or unusual diseases. His contribution consisted of relating cases in which the causation of the fever caused a good deal of difficulty. One was that of a middle-aged man who, when seen, had been ill four weeks. In one or two severe cases, with great œdema and ascites and effusions into the pleura, even large doses of iodine produced no effect at all. But when digitalis was substituted for the iodine a good effect was at once obtained. He had tried, in the out-patient department, giving iodine alone for a period of six months, but he had not been impressed with the result, and two he had brought into the ward to put them on to iodine treatment there, and they were subsequently operated upon.

With regard to the mechanism of exophthalmic goitre and how iodine was related to it, he was much interested in the work at Rochester in connexion with the possible presence in these thyroid glands of a substance differing from thyroxin. That work had not yet been published, but it seemed one of the likeliest explanations—namely, that in these cases there was a substance allied to thyroxin but differing from it, in which some of the iodine was replaced by some other compound.

Dr GUSTAV **MONOD** (Vichy) referred to the case of a woman, aged 45, who was admitted to hospital with a very definite complex of Graves's disease. She was submitted to X rays, but with no result. She then developed glycosuria, and she was given large doses of insulin for this, while retaining the normal diet. As expected, the diabetic symptoms cleared up immediately, and there was also a rapid improvement in all the exophthalmic goitre symptoms. After a few months, however, the patient developed pneumonia and died. He had found that cases of exophthalmic goitre were very tolerant of insulin. He wondered whether, in supplying insulin to the body, one was bringing about the same result as by performing thyroidectomy.

Prof F R. **FRASER** said that at the hospital he was attached to 50 cases of exophthalmic goitre had been treated with iodine in the last five years. At the beginning of that period there was no guidance as to dosage, hence, in a certain number of cases, harm was done. Doses of 30 ♏ of the 10 per cent. solution in alcohol a day were used, increased, in some instances, to 60 ♏, and in one case to 180 ♏ per diem. When harm was done it took two forms. One was the production of symptoms of iodism, the other was to cause a great enlargement and hardening of the thyroid gland and an exacerbation of the tachycardia, the palpitations, and the sense of choking. It was later found that results as good followed the use of smaller doses, and gradually the present scale of dosage was evolved. Mainly they used a 10 per cent. solution of iodine in 95 per cent. alcohol. Still, any ionised form of iodine answered equally well. Some people prescribed tincture of iodine which contained a large proportion of iodine as well as iodide. The particular preparation intended should always be specified. At St. Bartholomew's Hospital patients had been kept in bed and the severity of their symptoms of intoxication, their basal metabolic rates, &c., estimated, and then they were started on 5 ♏ of the alcohol solution three times a day. When the maximum result had been attained, the quantity was reduced to 10 ♏ a day, this being further reduced to 5 ♏ daily before the patient left the hospital, and this was the largest dose on which patients were allowed to leave the institution, otherwise severe exacerbations were liable to occur before they could be checked. He agreed that, however carefully watched, there were cases in which harm was done, and these were those of secondary Graves's disease. The dose for these had to be cut down to 2 ♏ a day; he believed every case of thyroid intoxication could be benefited if the right dose of iodine for that particular patient was ascertained. He agreed that cases of circulatory failure responded poorly to the treatment. He did not doubt that by means of iodine, carefully adjusted in this way, the disease ran its course at a lower level of intoxication than normally, and that if it was going to recover spontaneously it did so having run the milder course. He was also convinced that the treatment was most valuable in getting patients ready for surgery; also, it was very beneficial given for a long time after operation. He had not seen the severe crises referred to by Dr. McNee, but recently a girl was being given thyroxin intravenously. At first she improved a little, but after some days her pulse rose, she became excited, had tremor, and her level of intoxication rose. She was put on to iodine, and everything came down nicely in two or three days. He concluded by showing a number of charts of cases and relating their clinical histories.

Mr. T. P. **Dunhill** said that when a patient was very ill there was always a tendency for the surgeon to hope that he could stop the disease, or for the surgeon to be persuaded by the physician to operate against his better judgment. The operation for exophthalmic goitre should never be one of emergency; the patient should be in a proper condition for operation before such was attempted. After the preliminary iodine treatment already outlined had been given, there was not only less operative risk, but less blood was lost at the operation, and this was all to the patient's benefit after the operation. In the actual carrying out of the operation he found that in the iodised patient one could encroach more without harm on the region of the recurrent laryngeal nerve, and that it did not slip back in the loose cellular tissue. The iodine seemed to have changed the secretory stage to a colloid stage—i.e., the gland had reverted to a resting stage. In exophthalmic goitre there seemed to be produced a molecule, not that of thyroxin, which was poisonous, and hence the body was not receiving that which enabled it to carry on its normal metabolism. When iodine was given it did not stop the secretion of this poisonous substance but made up the iodine deficiency. He suggested that perhaps less of the gland could be removed than had been customary and yet secure as good a result, though he thought these patients never became quite normal again. Operation was nothing more than an expedient, and search for the cause of the condition should still be continued. Plummer did not claim that iodine would do good in every type of case; he said that in two-thirds of the cases the result was striking. In about 5 per cent. of the cases it was harmful. That seemed to be the general experience in this country too. The work of Scott Williamson and of Mellanby showed that there was a marked difference between the primary and the secondary types of goitre. In the primary there was very little fibrosis, in the secondary a great deal. Every grade between the two was met with. He warned Fellows against accepting such statements, as that all cases of exophthalmic goitre were so greatly improved by being given iodine that surgical operations on them became safe, or that the degree of preparation usually given to them had become unnecessary, or that after the operation they could safely leave the nursing home in five or six days.

Dr. J. A. **Ryle** spoke of the over-zealous attempt to find a specific method of therapy for a disease which was admittedly non-specific. He urged that there should be a more critical attitude adopted towards the problem. Very little was known of the causal pathology of this disease, and he believed that in producing the flare-up of symptoms many factors were at work—perhaps physical, metabolic, and infective. Certainly there was an emotional factor, both in its initiation and its perpetuation, and hence the search for a simple chemical answer should at least be undertaken with care. He did not dispute that iodine had a definite effect on certain cases of exophthalmic goitre, nor that salicylates produced an effect on rheumatic fever. But the pathological course of the latter was not influenced by salicylates. Sir William Hale-White had insisted on the importance of a study of the life-history of a disease when left to itself, and drew attention in the last discussion to the tendency of this disease to natural recovery. Indeed, very good figures resulted from "skilful neglect," and he had never yet felt called upon to ask a surgeon to help him with a case. Summing up his attitude on the subject, he said he preferred to treat a case with optimism rather than with iodine.

Dr. E. G. **Calvert** said that in the last three years he had treated 60 cases of exophthalmic goitre with iodine, and he agreed as to its beneficial effects. Coincident with the improved clinical condition of the patient he noted that the gland became firm, and if the iodine was pushed so that the gland became of stony hardness the results were not of the best. The best results ensued from giving from 3 to 7 ♏ of Lugol's iodine. He exhibited photographs of cases and gave the details of the treatment pursued in each case, with the clinical results.

The **Chairman** said it had become evident that, though iodine could do much for patients suffering from exophthalmic goitre, it might prove for some, especially if the dosage was not correct, a very dangerous drug. He alluded to the desirability of setting up some standard preparation with a known iodine content. He also referred to the value of large doses of iodine for acute tonsillitis with auricular fibrillation in association with exophthalmic goitre, and related a case in point.

*(To be continued.)*

# ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

A meeting of this Association was held in London on Feb. 16th, Sir **Frederick Mott**, the President, being in the chair. After resolutions of condolence with the families of the late Dr. Henry Rayner and the late Dr. W. D. Moore had been passed, Dr. **Isabel Robertson** read a paper on

### *Blood and Vascular Conditions in Psychoses.*

She recapitulated certain observations on the hæmoclastic crisis in psychoses, and submitted the results of further work on the effect of hyoscine and adrenalin on the production of that crisis in encephalitis lethargica. The reaction, she contended, was real and was not related to such factors as normal variations in the leucocytes, and was able to show that reversals of reaction occurred under the influence of sympathetico- and para-sympathetico-ministic drugs. The crisis was characterised by leucopenia, fall of blood pressure, inversion of the leucocytic formula, hypercoagulability of the blood, and diminution of the refractive index of the serum. To demonstrate its presence 200 g. of milk was administered to a subject who had fasted since the previous night. The leucocytes, differential leucocytes, and blood pressure were noted before the taking of the milk, and at intervals of 20, 40, and 60 minutes after it. The maximum disturbance was generally at the 40-minute interval. In 50 well-marked cases of dementia præcox of all types and at all ages 94 per cent. reacted to the ingestion of milk by a definite hæmoclastic crisis. In 70 per cent. of these the leucopenia was accompanied by a fall in blood pressure of from 3 to 12 mm. of mercury. In cases of melancholia, acute and chronic, 75 per cent. definitely gave the crisis, 15 per cent. a normal leucocytosis, and 10 per cent. an indeterminate result; 55 per cent. of the mania cases examined showed the hæmoclastic crisis, 20 per cent. gave a normal leucocytosis, and 20 per cent. an indeterminate result. Commenting on a paper by Dr. A. F. B. Shaw,[1] in which the crisis was discussed as a test for liver function with special reference to leucocytic changes, Dr. Robertson said that Dr. Shaw's paradoxical results were similar to those she obtained and termed intermediate. She found that the general effect of heat in normal subjects was to cause a leucocytosis, but if the heat were intense there was a leucopenia. Similarly, ordinary cold caused leucopenia, but prolonged cold caused leucocytosis. The leucocyte count could be affected by psychic and emotional disturbance, and the variations might be both rapid and intense. With care and proper technique, however, it was possible to obtain leucocytic equilibrium within an hour.

---

[1] Brit. Med. Jour., 1925, i., 914.

Investigations had been made in 275 early psychotic cases ranging from the milder neuroses to the more acute forms of mental trouble; 49 per cent. showed the hæmoclastic crisis, 12 5 per cent. gave an intermediate reaction, and 38 5 per cent. reacted normally by a leucocytosis; 50 per cent. of the intermediate ones showed the hæmoclastic crisis later. There seemed to be some prognostic value in the presence or absence of the crisis in these cases. Investigations on the ingestion of milk following the administration of adrenalin, atropine, and pilocarpine showed that adrenalin and atropine could convert the leucopenia into a leucocytosis, though neither had any influence on the leucocytosis occurring in the normal subject The effects of pilocarpine were too varied to permit of a statement being made. Administration of thyroid caused a reversal of the reaction; it produced the crisis in a normal subject.

### *Hæmoclasia and Encephalitis Lethargica.*

Dr. Robertson said that 13 of 15 cases of encephalitis lethargica reacted to ingestion of milk by a definite leucopenia, the other two by a leucocytosis. The effect of the subcutaneous injection of hyoscine on the encephalitic cases was a leucopenia in all except one. In the cases of chorea the drug caused a marked leucocytosis in four, a slight leucocytosis in one, and a leucopenia in one. Thus the tendency was for the effect of hyoscine to resemble the response to milk, though this did not hold absolutely.

In the investigation of anaphylaxis it was established that certain phenomena occurred at the time of, or just before, the onset of anaphylactic symptoms. The most important were a fall in the leucocyte count, a drop in the arterial blood pressure, hypercoagulability of the blood, and a diminution of the refractive index of the serum. This crisis was demonstrable in asthma, paroxysmal hæmoglobinuria, epilepsy, and other conditions. Anaphylactic shock, Dr. Robertson said, was not due to a specific poison, but could appear as a result of a physical process. Schiff had shown that a marked eosinophilia occurred in the blood during anaphylactic shock. There seemed to be a similarity between hæmoclasia and anaphylaxis. Gluser had found that after an active dose of adrenalin or atropine the leucopenia following the ingestion of milk could be converted into a leucocytosis, and that in a normal person pilocarpine converted the leucocytosis into a leucopenia, his conclusion from this being that the hæmoclastic crisis was a change in the equilibrium between vagus and sympathetic tonus. Hæmoclasia occurred after glucose in practically every case of diabetes, but after the ingestion of milk in less than 50 per cent. In her summary Dr. Robertson said that hæmoclasia occurred in 94 per cent. of cases of dementia præcox, 85 per cent. of melancholias, 75 per cent. of manias, and 88 per cent. of encephalitis. The blood changes were in the venous blood as well as in the blood at the periphery She suggested that a condition of anaphylaxis existed in cases showing hæmoclasia, and that this condition depended on the condition of the sympathetic nervous system.

### *Discussion.*

Dr. F. L. GOLLA agreed that the reaction was one that could be obtained with unfailing accuracy when certain precautions were observed. But those who hoped to discover by this reaction some form of mental or nervous disease were doomed to disappointment. It was a simple phenomenon, uncomplicated by the ingestion or absorption of foreign proteins. In one case Dr. Robertson had found that it varied according to whether the patient was standing up or lying down, and reversals could be obtained by administering adrenalin or thyroid extract. The bronchi and the musculature of the lungs were also involved in the reaction; if the bronchi were contracted, as in asthma, there was one reaction; if they were dilated, there was a reversal of that reaction, and the same was true of the sympathetic nervous system elsewhere. A minute dose of adrenalin caused relaxation; a larger dose was followed by constriction. The reactions depended on the state of the receptive organ The reaction was not diagnostic, but it showed that an organ was in a certain state of either equilibrium or dysequilibrium. It also seemed that it would be of value in prognosis. At the bottom of nervous conditions there seemed to be a maldisposition of the vegetative nervous system.

Dr A A W. PETRIE said that in his experience a high proportion of anxiety cases gave a positive reaction, perhaps largely because they returned to hospital after a trying time at home. A very high proportion of cases of dementia præcox gave the reaction He agreed that the test promised to be of great assistance in prognosis; it might show with fair truth what cases were likely to pass into the certifiable stage.

The PRESIDENT said that this was a very important piece of work in showing the dysequilibrium of the vegetative nervous system which was common to all cases of psychosis. Owing to a change in the hydrogen-ion content of the blood, he thought the surface tension of the fluid might be altered, so that the leucocytes adhered more to the sides of the vessels.

---

## NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

AT a meeting of this Society held in Sheffield on Feb. 10th, Mr. W. GOUGH (Leeds), the President, occupied the chair, and Mr. A. LEYLAND ROBINSON (Liverpool) showed an

### *Ovarian Cyst*

removed from a healthy, well-developed girl of 11 years.

She complained of abdominal discomfort for one week, and on examination her doctor discovered a tumour extending up to the umbilicus, which had all the physical signs of a simple serous cyst. A vaginal examination made under anæsthesia immediately before operation disclosed typical dermoid consistency of the lower pole of the swelling, and suggested the dual pathological nature of the tumour. Removal was easy, and convalescence uneventful. It was noticed at the operation that the uterus was narrow and elongated, probably as a result of pressure from the tumour, and perhaps of hypofunction of the ovary. The external genitalia were normal.

The specimen proved to be a bilocular cyst, the lower loculus showing the usual characters of a dermoid, and the upper one those of a serous cyst adenoma.

These cases, said Mr. Robinson, were not very uncommon in children under 10 years of age. Bland-Sutton had collected 100 cases, and Howard Kelly had published 126 in 1901, of which 55 were unilocular or multilocular cyst adenomata, 47 were dermoids, and 24 were solid tumours of the ovary. Many tumours had been successfully removed from quite young infants. D'Arcy Power had operated on a child of 4 months, and MacGillivray in 1908 had described a very interesting operation at which he successfully removed a cyst which completely filled the abdomen of an infant of 11 months. The chief points of interest in the present case were the association of a dermoid cyst with a serous adenoma, the almost complete absence of symptoms, which were generally those of an acute abdomen and due to torsion, and the attenuated appearance of the uterus. Possibly there would be persistent infantilism as a result of the loss of the left ovary, which might offer an excellent opportunity for the use of glandular extracts during pubescence.

### *Tumours of the Vulva.*

Mr. Robinson also reported two cases of tumours of the vulva which were sent to hospital with a diagnosis of Bartholin's cyst. The first, in a single multiparous woman of 33 years, proved to be a fibromyoma of the vulva; it would be called a dermoid by some pathologists. These dermoids were described as connective-tissue tumours of the female abdominal wall, which display active growth during pregnancy and have a pathological relationship to the fibrosarcomata. The probability was that they were merely fibromyomata arising in the round ligaments, or some outlying or displaced rest of myometrial tissue, which grew in unison with the uterine muscle during pregnancy. The cellular appearance produced by this decidual or pregnancy reaction had been mistaken for malignancy, and had led to the incorrect inclusion of these tumours amongst the sarcomata. The second tumour was a carcinoma of Bartholin's gland.

The patient was a widow of 55 years of age, 17 years past the menopause, with no history of gonorrhœa or any serious illness. There had been four abortions, the last 20 years ago, and no full-term labours. The patient complained of some dragging pain in the vagina and of a lump in the vulva which was first noticed four months before seeking advice. It had been getting bigger lately.

A swelling the size of a hazel nut was found in the right labium majus, in the anatomical position of Bartholin's gland. It was slightly tender and solid in consistency. The overlying skin was perfectly normal in appearance and mobility. No glands could be felt in either groin. Local excision only was done, partly because the patient's general condition was very poor and partly because the diagnosis of malignancy rested on suspicion alone. There were no enlarged glands, and it was thought that as this type of malignant disease is very rare, the lump might turn out to be a simple adenoma.

A small secondary hæmorrhage occurred on the ninth day of convalescence, but otherwise the patient made a smooth recovery, and remains well at the present day, seven months later, during which time she has been under treatment by X ray therapy.

In 1913, said Mr. Robinson, Dr. Herbert Spencer had published a similar case, and had included in his paper 13 which he had been able to collect from the literature, of which only one had been published in English journals. Spencer stated that these tumours are harder than an inflamed gland, nodular on the surface, and associated with bluish discoloration of the skin and œdema of the hymen; but 14 cases were too few to dogmatise on, and practically none of these points were seen in his, Mr. Robinson's, case. Of the 14 examples collected by Spencer, in one only had there been any positive history of gonorrhœa, and in only three was leucorrhœal discharge a feature; so that previous infection had little, if any, ætiological significance. Congenital abnormality had been noticed in two cases, Bartholin's gland being apparently absent on the side opposite to the tumour. The pathological appearances varied greatly, and little agreement existed amongst the 14 authors. In three cases the growth was described as carcinoma only, in two as cylindrical carcinoma, and in the remainder as follows: *Melano-carcinoma*; *tubular carcinoma, partly scirrhus*; *carcinoma parvi cellulaire*; *cancroise carcinoma*; *adeno-carcinoma*; *villous carcinoma*; *squamous-celled carcinoma*; and *adeno-carcinoma, resembling squamous*. Spencer pointed out that the pathological differences were associated with the fact that the epithelium lying around the acini and ducts varied considerably in shape and arrangement, and hence the gland might well give rise to tumours of diverse appearances. He quoted Jambon and Chaboux, who had examined the glands of several young adults after death. They stated

> "that the excretory ducts appear in the middle of the gland in the form of irregular cavities, reaching even to the middle of the acini. They present an epithelium either of one or several layers of cubical cells Generally, as the duct increases in calibre and importance, its epithelial lining becomes thicker. The cells are only half the size of the secretory cells of the acini, and consist of a large nucleus surrounded by a thin layer of granular protoplasm; near the termination of the common duct the superficial layers of the lining epithelium tend to become squamous."

These authors say nothing about distinctly cylindrical epithelium in the duct, though this is mentioned by de Sinety, Klein, and Langerhans. In the present case there could be no doubt that the tumour was an adeno-carcinoma. These growths were said to be of great malignancy, and of the 14 cases mentioned by Spencer only one survived six years after operation. "It is interesting to note," said Mr. Robinson, "that in this case, as in my own, no glands were removed. I hope to report the progress of the case to the Society at some later date."

### *Chronic Inversion of the Uterus.*

Dr. D. DOUGAL (Manchester) reported the following case.

Mrs. H., married, aged 24, complained of constant bleeding which began six weeks after confinement 14 months previously. At the confinement the child was born without interference, but the placenta had to be removed manually. She states that she was much shocked at the end of the labour, and her convalescence was slow. She was extremely anæmic, and on vaginal examination a soft swelling was felt protruding through the cervix. This tumour bled a good deal on being handled. The fundus of the uterus could not be felt in its normal position, and chronic inversion was diagnosed.

Attempts to reduce the displacement with repositors, both Aveling's and another, were unsuccessful, and it was decided to use surgical means. Spinelli's operation was chosen. This is really an extensive anterior hysterotomy, but in this case it was somewhat awkward to carry out owing to the inverted structures. The anterior wall of the uterus had to be incised as high as the fundus before it was possible to reduce the displacement. There were no adhesions present at the neck of the sac, but the peritoneal surfaces about the fundus were adherent to one another; the remains of a partially atrophied fibroid, about the size of a bean, were found on separating the adhesions. This tumour was excised, and the uterus stitched up. There was a good deal of oozing which could not be completely controlled, and so a narrow gauze drain was left in contact with the anterior uterine wall. The vaginal wall was then sutured in the usual way, a small part being left open for the gauze to pass through.

The patient made an uneventful recovery, and is now, three months later, menstruating regularly and losing a normal amount of blood at the periods.

The inversion, Dr. Dougal said, might have been caused by extracting a partially separated placenta; but, on the other hand, it might have been spontaneous, the fibroid tumour at the fundus of the uterus playing some part in the process. The failure to replace the uterus with the repositor had no doubt been partly due to the fact that the anterior and posterior surfaces of the uterus were adherent in the neighbourhood of the fundus.

### *Ruptured Uterus.*

Dr. C. P. BRENTNALL (Manchester) reported a case of ruptured uterus in a woman, aged 38 years, in her sixth pregnancy.

The first four labours were normal and at full term; the fifth was premature, and the child was stillborn. There was a minor degree of pelvic contraction; the transverse measurements were normal, and the conjugate slightly reduced. The external conjugate measured less than 7 inches. There were no abnormalities during pregnancy, and labour began about the estimated date. Pains began at 8 A.M., and continued until about 5.30 P.M. They do not appear to have been severe; there were long intervals between them, and the woman was still going about the house when her husband returned from work at 5.30. Shortly afterwards the membranes ruptured, the uterine contractions recommenced, and she took to her bed. She says that she bled a good deal during the evening, but this is doubtful as the midwife did not send for a doctor until about midnight. The pains continued without intermission until 2.30 in the morning. She was seen by two doctors about midnight, and was immediately sent to hospital with the diagnosis of impacted breech. There appears to have been no attempt at any operation.

She arrived at hospital at 2.30 A.M. Labour had then lasted 18½ hours, and the membranes had been ruptured nine hours. She was very pale and shocked. Abdominal examination revealed the obvious fact that the uterus was ruptured. The body of the fœtus could be felt to one side and the contracted uterus to the other. The lower abdomen was very tender, and she complained of pain in the left shoulder. The fœtal head was quite low down in the pelvis, lying in the transverse diameter, and there was a depressed fracture of the posterior parietal bone. The fœtus was delivered by craniotomy, and the placenta removed manually. It seemed doubtful whether the woman would stand an abdominal section, but it appeared to be her only chance. When the abdomen was opened a longitudinal tear of the uterus was discovered, extending from the attachment of the round ligament, and involving the upper part of the vagina. Both layers of the broad ligament were torn across, but the Fallopian tube and infundibulo-pelvic ligament were intact. The uterus was removed as rapidly as possible by panhysterectomy, and the vaginal wound closed. The pelvis was drained by a rubber tube in the lower angle of the incision.

Dr. Brontnall remarked that there were one or two unusual features about the case. Ruptures of the uterus were, of course, of more frequent occurrence in the minor than in the major degrees of contracted pelvis, and they were commoner in multiparæ than in primigravidæ. But in such cases there was generally a history of dystocia, and the supposition was that some undetected injury to the soft parts gave way at the subsequent labour. In this case the pelvic contraction was of a very minor degree, the pelvis being of the simple flat variety; and all the previous confinements had been completed without difficulty or undue delay. There was no early rupture of the membranes, and if it was assumed that the second stage of labour began when the waters broke, its total duration had been not more than nine hours. The most unusual feature of the case appeared to be that the head had passed the brim and was well down in the pelvis.

Amongst other contributions to the meeting was a note on two cases of Wertheim's hysterectomy complicated by double ureter, by Prof. W. FLETCHER SHAW (Manchester).—The PRESIDENT showed a specimen of carcinoma of the cervix from a patient aged 20, and Prof. SHAW reported having seen the condition in a woman of 22.—Prof. J. S. C. DOUGLAS and Mr. W. W. KING (Sheffield) demonstrated a specimen of mucocele of the appendix.—Mr. KING described a case of adenomyoma of the uterus, and Dr. DOUGAL gave an account of a case of double placenta in which there was placenta prævia, and marginal and velamentous insertion of the cord.

---

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF SURGERY.

AT a meeting of this Section held on Feb. 10th, Mr. R. C. B. MAUNSELL, *the President, took* the chair, and Mr. W. E. MILES (London) read a paper on

### *Carcinoma of the Rectum.*

He said that he had treated 587 patients for this condition, in 311 of whom the disease had come on between the ages of 50 and 60; the incidence had been almost equal in men and women. There was only one type of cancer of the rectum—an adenocarcinoma. But there were three varieties of carcinoma which were recognised clinically and which differed in malignancy—the papilliferous type, the adenoid type, and the colloid degenerative type. In the first, which was the least malignant kind, involvement of the glands was seldom found; even after a restricted operation the growth was not apt to recur. This type was not as common as the others. The adenoid type was much more malignant. There were always infiltrations, and only an operation which aimed at removing the vulnerable tissues would protect a patient against recurrence. The colloid type affected the connective tissues. It was the most malignant type of cancer, and practically always recurred, even after the most drastic operation. These three varieties of carcinoma might be met with in any part of the rectum.

Referring to symptoms, Mr. Miles said that if attacks of alternating constipation and diarrhœa were waited for, a case might be missed which would otherwise be amenable to treatment, for sometimes these attacks did not occur until the disease was very far advanced. The position of the cancer made a difference to the rapidity with which they developed. There might, however, be actual difficulty in obtaining an action of the bowels at all, and this was an urgent symptom. Ampullary growths might persist for a considerable time before they produced enough symptoms for notice. If the liver was involved in a case of cancer of the rectum it might be taken for granted that the growth had penetrated the peritoneum, and that operation was now contra-indicated. It was impossible to say how long these growths might exist without producing any symptoms, but certainly they might be present for six months before any symptoms showed themselves. The extent of the circumferential involvement was an index of the depth of the growth and of the length of time the disease had been present. The operability or inoperability of a case could not be estimated by digital examination alone, and it was absolutely necessary to open the abdomen and see what the condition of extramural extension was. The dissemination of cancer from the extramural lymphatics was slight.

The PRESIDENT drew attention to the lack of symptoms in rectal cancer, except when the growth was low down near the anal canal, when the pain was very severe.

Sir WILLIAM TAYLOR said that there was only one scientific method of dealing with the condition, and that was the combined abdominal and perineal operation. It was undesirable, he agreed, to estimate the operability by digital examination alone; secondary deposits in the liver could sometimes only be detected by laparotomy and examination of the upper surface of the viscus. Carcinoma of the rectum seemed relatively uncommon in Irish practice, but in his comparatively limited experience only one case in six was operable. At the Mayo Clinic recently he had seen six cases operated on within two days by the parasacral method after preliminary colostomy. The mortality rate for this procedure was, he believed, about 5 per cent.; but the operation now done at the Mayo Clinic was the combined abdominal and perineal one.

Mr. SETON PRINGLE said that there was only one really radical operation for carcinoma of the rectum, and that was the combined abdominal and perineal operation. The immediate mortality might be high, but the cases which got over the operation had a reasonable chance of permanent recovery.

Mr. H. F. MACAULEY said that he thought the vast majority of cases of carcinoma of the rectum seen in Dublin were inoperable. Frequently he found nodules in the liver, and could not go on to further operation.

Mr. H. S. MEADE said that in the last ten years he had seen 46 cases of carcinoma of the rectum, of which 26 were inoperable. Eleven of these, though operable, had refused operation because colostomy had been done. Of the other inoperable cases two survived and were getting deep X ray treatment. He had operated on 20 cases. In the first eight he had done the perineal operation, and all of them were dead except one. In the remaining 12 he had used the combined abdominal and perineal method; seven had died but the other five were still alive.

Mr. MILES, replying, said that even in early cases only the biggest possible operation gave the possibility of safeguarding against recurrence. In obstructive cases he always performed cæcostomy.

## SECTION OF PATHOLOGY.

AT a meeting of this Section held on Feb 12th, Prof. J. W. BIGGER, the President, read a communication on the Tests for Yeasts used in Baking. The production of baking yeast, he said, was now almost a separate industry from that of yeast for brewing

He discussed the qualities desirable in baking yeast and the tests for estimating them.

Mr. R. A. Stoney and Dr. J. T. Wigham showed a specimen of sarcoma of the testis from a man, aged 30, with a previous history of phthisis. The earliest sign had been a swelling of the epididymis, which was clinically indistinguishable from a tuberculous epididymitis.—Dr. W. Boxwell showed specimens of sarcoma in lungs and brain, secondary to a round-celled sarcoma of the testis removed nine months previously. —Dr. W. D. O'Kelly showed a chorion epithelioma, and Dr. N. Falkiner showed some plates which he had presented to the School of Physic.

## EDINBURGH OBSTETRICAL SOCIETY.

At a meeting of this Society held on Feb. 10th Dr. R. W. Johnstone, the President, took the chair, and Dr. James Young read a communication on the

### *Embedding Changes in the Uterine Mucosa as Studied in an Early Human Ovum.*

The ovum, he said, was situated in a completely closed implantation chamber, but extending from its outer surface through the entire thickness of the mucous membrane there was a narrow stalk of trophoblast which indicated the track of entrance. Externally it measured 1·5 × 0·77 × 0·6 mm., and the trophoblast consisted of the usual dual cellular elements. There was no evidence of the vacuolation of the syncytium present in the Bryce-Teacher ovum, which he believed to be probably abnormal. The blastocyst measured 0·44 × 0·3 mm.; it was filled by mesoblast and there were no villi. The embryonic area was too badly damaged to allow of a satisfactory study. The ovum in its general features resembled the two earliest ova so far described—namely, those of Miller and Kleinhans. The maternal changes were similar to those which Dr. Young had described in 1910. To understand these changes it was necessary to remember that the uterine mucous membrane was unique amongst the tissues of the human organism in so far as its function, both during the menstrual cycle and during pregnancy, was fulfilled by a discharge of blood from its vessels. The mucosa thus bled in anticipation, and it bled again with realisation. Despite the unique character of this phenomenon it had often been believed that the menstrual bleeding and the bleeding of pregnancy were necessarily two different processes. In one case it was due to the ovarian hormone, whilst in the other it was thought to be due to the active destruction of the vessel-walls and the mechanical liberation of the blood. But if the bleeding that was essential to placentation could be accomplished in this mechanical way, why then, it was asked, had there been built up all the physiological and structural complex, whose obvious function was an immediate opening up of the vessels and a discharge of the blood at the very regions where the ovum could be expected to appear?

In his previous work Dr. Young professed to have solved this obvious dilemma by showing that the bleeding of the menstrual cycle and the bleeding round the engrafted ovum were essentially similar and were due, in each case, to the response of a specially constructed and specially sensitised tissue to a biochemical material. He had shown that during pregnancy the vessels open up in a way which is exactly similar to that operating in the pre-menstrual phase. His views, published 16 years ago, on the essential similarity of the menstrual and placental hormones in so far as the uterine changes were concerned were supported by the recent work of Allen and Doisy and others, who had shown that pre-œstral changes in ovariectomised animals can be induced by both ovarian and placental extracts. Dr. Young had previously shown that the ease with which this "bleeding" response occurred was due to the fact that the stroma of the mucosa consists of a soft undifferentiated tissue, in which the vessels are devoid of any supporting elements, muscle, fibrous, or elastic tissue.

The nature of the maternal reaction in his present very early ovum confirmed his previous results. In a wide zone round the implantation chamber the vessels were expanded in a sinus-like manner and in areas distant from the trophoblast their contents were being poured freely into the stroma. The result of this bleeding response to the chorionic secretion was a virtual advance of the nourishing blood fluids towards the ovum, and, in the immediate vicinity of this, a pouring of the blood into the implantation chamber from vessels, which were thus like rivers that had overflowed their banks. Only by an understanding of these phenomena could we appreciate the function of the decidua. It was obvious that these maternal changes were temporary and had as their sole purpose the needs incidental to embedding. After this was accomplished and a sufficient blood-supply was provided, it was clear that the active displacement of tissue which they implied had to be arrested. This later and entirely different phase in placentation could only be possible in one or other or both of two ways—by a suspension of the chorionic secretion or by a protective mechanism on the part of the maternal tissues. Dr. Young in this connexion showed sections of pregnant tubes in which the only regions where the tissues were protected against a tearing up by the œdematous and hæmorrhagic escape provoked by the chorionic secretion were the regions, in the mucous membrane, where a decidual reaction had occurred. He believed that in the uterus in normal pregnancy the decidua acted in a similar way. A recognition of these facts could alone explain why the whole mucosa —that is, the whole of the sensitive tissue—must necessarily undergo a decidual change.

## LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

### *Sanocrysin.*

At a meeting of this Society held on Feb. 26th, with Mr. A. L. Whitehead, the President, in the chair, Prof. T. R. Elliott (London) read a paper on Sanocrysin in Tuberculous Infections. He gave a résumé of the British and foreign experience of this drug, pointing out that it was now given in smaller doses than at first, so that dangerous reactions should be avoided. It was possible, he said, that this gentler method of using sanocrysin was less effective in arresting the disease. In the discussion which followed Prof. Elliott expressed the opinion that it was unlikely that the drug would prove useful in lupus. He did not feel that its use was justified in cases of renal tuberculosis.

---

Donations and Bequests.—The late Dame Louisa Brandreth Aldrich-Blake left by will, among other bequests, £1000 and all her medical and surgical instruments and appliances to the Elizabeth Garrett Anderson Hospital for Women, Euston-road, N.W.; £1000 to the London (Royal Free Hospital) School of Medicine for Women, for the Endowment Fund; and £1000 to the Royal Free Hospital.—Mr. George Duckworth Atkin, of Lindfield-gardens, bequeathed by will, in addition to other legacies, £105 each to the London Hospital, Charing Cross Hospital, St. Bartholomew's Hospital, the Royal Free Hospital, University College Hospital, the Middlesex Hospital, the Royal Orthopædic Hospital, and the Chelsea Hospital for Women; £52 10s. each to the Royal Eye Hospital, the Poplar Hospital for Accidents, and the Paddington Green Children's Hospital.—Mrs. Emily Topham, of Hunthill, Folkestone, who left estate of the gross value of £247,700, besides other bequests, gave £1000 each to the Westminster Hospital and Dr. Barnardo's Homes, and the ultimate residue, which will amount to about £120,000, equally between the Westminster Hospital, the London Hospital, and St. George's Hospital, in each case for the benefit of diabetic patients, directing that any hospital interfering with the discretion of her trustees or commencing an action to dispute such should forfeit all interest under her will.—Mr. E. Cecil Jones has given £10,000 towards a children's section of the new hospital for Southend-on-Sea as a memorial to his late father, Mr. R. A. Jones. Lord Elveden has given £20,000 and a site of 12 acres.

# Reviews and Notices of Books.

### INFANT WELFARE.

*Modern Methods of Feeding in Infancy and Childhood.* By DONALD PATERSON, M.B., M.R.C.P., and J. FOREST SMITH, M.R.C.P. London: Constable and Co. 1926. Pp. 106. 7s. 6d.

THE latest volume of the Modern Medical Monographs, edited by Prof. H. MacLean, is devoted rather more completely to the feeding of the infant than is indicated by the title. The authors have presented the subject in a scientific and impartial manner, recognising the fact that no type of infant feeding has proved universally successful, and that good results are obtained by a number of different methods. The part played in nutrition by the various components of milk, and the composition of different infant foods, are clearly set out in the first chapter. In dealing with artificial feeding the authors give an account of four methods: whole milk, humanised milk with a single formula, percentage feeding, and simple dilution with addition of carbohydrate. The merits and disadvantages which they have found to be associated with each are indicated; they suggest simple dilution with addition of carbohydrates as the method of choice for the majority of bottle-fed infants. The weight rather than the age of the infant is taken as the indication for weaning, mixed feeding being recommended as soon as the child reaches 15 lb. One of the great merits of this book lies in its recognition of the importance of providing students and practitioners with regimes which are simple enough to be universally practicable; it may be recommended to all who wish to obtain a well-balanced idea of this much discussed subject.

*Diseases of Infants and Children.* By H. D. CHAPIN, M.D., Professor of Diseases of Children, New York Post-Graduate Hospital; and L. T. ROYSTER, M.D., Professor of Pediatrics, University of Virginia. London: Baillière, Tindall and Cox. 1925. Pp. 633. 30s.

THE fifth edition of Chapin and Pisek's text-book has been brought out by Dr. Chapin in collaboration with Dr. Royster. A large part of the book has been rewritten, and much new matter has been added. A considerable portion of the book has been devoted to infant feeding and the diet of children. For artificial feeding of infants the authors favour an extremely low fat content, and are impressed with the advantages of lactic acid milk. An excellent account is given of the infectious fevers, illustrated by some realistic colour-plates. Diseases of the nervous system are treated perhaps too briefly; a few statements are found which will not escape challenge, such as that the movements of chorea are produced by irritation of the Rolandic area. Recent work on the biochemistry of rickets has been included; the authors adhere firmly to the dietetic view of its causation. Some complicated differential diagnoses, such as those of the anæmias and splenic enlargements, are very clearly presented in tabular form.

The book is well illustrated and of convenient size, and may be recommended as an admirable text-book for students and practitioners.

### LOCAL ANÆSTHESIA OF THE FACE AND NECK.

*Lehrbuch der Lokalanästhesie des Ohres, &c.* By Dr. CÆSAR HIRSCH, Chief Surgeon to the Throat, Nose and Ear Department, Marienhospital, Stuttgart. Stuttgart: Ferdinand Enke. 1925. Pp. 203. M.25.

IN this book Dr. Hirsch provides a very thorough account of local anæsthesia as applied to operative work on the ear, eye, nose and accessory sinuses, face, mouth and pharynx, neck, larynx, trachea, and œsophagus. After a preliminary consideration of the object of, and indications for local anæsthesia, and of pain in general, a short history of the subject is given; then follows a full description of cocaine, its chemical constitution, its action, and its pharmacology. Some of the cocaine-substitutes are similarly dealt with, notably, alypin, novocain, psicain, and tutocain; of these the author rightly states that the earlier pronouncements on the safety of alypin have not been justified, but he obtains satisfactory results with all the other four drugs. For surface application to the mucous membranes he finds that potassium sulphate, carbolic acid, and suprarenin all enhance the effect of cocaine, and advises cocaine 8 parts, sulphate of potash (3 per cent. solution) 20 parts, adrenalin (1 in 1000) 10 parts, carbolic acid solution (½ per cent.) to 100 parts, which he states to be equal in potency to a 10 per cent. ordinary solution of cocaine. Phenol also increases the potency of tutocain, while sulphate of potash does not, and a perfect anæsthesia of the larynx is obtained by a 5 per cent. solution of tutocain with adrenalin and phenol; psicain is used similarly in 2 to 4 per cent. solution, while novocain is not considered satisfactory for surface application. For injection novocain is preferred in ¼ to ½ per cent. solution; the solvent solution is made up of sodium chloride 7 parts and potassium sulphate 4 parts, to 1000 parts of water, to which 3 to 5 drops of dilute hydrochloric acid are added to neutralise the absorption of alkali from the glass if the solution has to be kept for a long time. Adrenalin is added in the proportion of 1 drop per cubic centimetre. Tutocain may be similarly employed in half the strength at which novocain is used. Cocaine has been abandoned for injection, and psicain is not mentioned for this purpose; the quinine derivatives are rejected on account of their harmful effects upon the tissues. The greater part of the book is occupied by descriptions of the technique of obtaining local anæsthesia for practically every operation on these regions; these are admirably complete and are profusely illustrated. A good index and a bibliography are provided.

Dr. Hirsch has produced an invaluable and indispensable work of reference on an important subject.

### MIND AND MEDICINE.

By THOMAS W. SALMON, M.D., Professor of Psychiatry, Columbia University. New York: Columbia University Press. Pp. 34. 5s.

THIS short lecture, delivered at the opening session of the College of Physicians and Surgeons at Columbia University, surveys the modern attitude of medicine towards the problems of the mind, and pleads for the impartial recognition of mind, will, and personality as factors equal in importance to the processes of physiology and biochemistry. Dr. Salmon suggests that the physicians of 70 years ago recognised no such cleavage between body and mind as do the pathologists and biologists of to-day, and that the "deadly parallelism" which practically excludes mental disorder from general medical interest springs from the wealth of new methods of investigation, and the resulting attitude that no real functional disorder can exist without an observable structural defect to account for it. There are many able men in this country who hold the same views as Dr. Salmon, and there is every prospect that the problems of mental disease will before long regain the prominence that their importance so urgently demands.

### THE GREAT ABNORMALS.

By THEO. B. HYSLOP, M.D., F.R.S.E., Gaskell Scholar in Psychological Medicine, &c. London: Philip Allan and Co. 1925. Pp. 280. 8s. 6d.

Dr. Hyslop gives a history of some of the great ones of the earth whose mental abnormalities have been disastrous to mankind, of others whose genius was joined to eccentricities that, but for the chance that placed them in other times than ours, would have led to their confinement as insane, and he also describes epidemics of irrational beliefs and behaviour that leave the uncomfortable feeling that perhaps there is no guarantee that civilised man may not relapse into similar error. The vagaries of despots like Ivan the Terrible, the effects of mass suggestion as shown in the Crusades, in witchmania and alchemy, are more interesting than encouraging, and in a chapter on the early history of Bedlam the author reveals his belief that the world outside differs little in its methods and sentiments from the world inside. Studies of visionaries, of whom Swedenborg stands as a type, and of the foibles of men of genius, complete this historical survey. The conclusions to be drawn from the material presented are not clear, but the reader will make acquaintance with a vast range of mental abnormality that has existed without contemporary recognition of its pathological nature.

## JOURNALS.

Journal of Industrial Hygiene. February, 1926.—The use in America of tetraethyl lead in motor spirit to increase its explosive power is said to be introducing a new health hazard. The subject has been investigated by F. B. Flinn, of Columbia University, who experimented on a number of different animals, testing them for skin absorption, and also by exposure to fumes of the fortified spirit. After an exhaustive inquiry, which is reported in detail, he concluded that the lead compounds can be absorbed faster than the lead can be excreted. Definite malaise may occur and prolonged exposure to such risk must constitute a health hazard. He also found that animals absorbed lead from the fumes, and that the effects were obtained more rapidly than by skin absorption. The fortified spirit placed on sale used to contain 1 part of the lead compound to 1000 parts of spirit, but the vendors have already altered the mixture to 1 part in 1300. The whole question has been causing considerable interest in the United States.—Some interesting cases of occupational poisoning by mononitrochlorobenzene are reported by A. Renshaw and G. V. Ashcroft. Four cases were carefully observed in hospital. They exhibited a peculiar slate-grey and cyanotic appearance, and suffered from dyspnœa, collapse, and throbbing in the head; the breath smelt of oil of bitter almonds, and the blood was of a peculiar chocolate colour. Men collapsed after about three days' work, and apparently the poison was absorbed as a vapour through the lungs. The symptoms are ascribed to anoxæmia due to the hæmoglobin of the blood being attacked and to its oxygen-carrying powers being diminished thereby. There was some anæmia due to interference of the function of the bone-marrow.—An account is given by L. Noland, of the organisation of the industrial health department of the Tennessee Coal, Iron, and Railroad Company, which employs some 23,000 persons, and houses them as well. The company embarked upon a health programme in 1913, and now has a staff of seven sanitary inspectors attending to the water-supply, sanitary conveniences, mosquito control, fly protection, food- and milk-supplies, and bath houses of the community. It also has a force of 46 whole-time doctors, who examine all new workers, and men who have been absent for 15 days or more when they resume work. As many as 206,223 patients were treated at dispensaries in 1924; 92,032 calls were made on the homes of the workers, and 26,252 examinations of new or re-employed men were made. There are 14 whole-time dentists, who find it impossible to do all the work brought to them. The company also keeps up a hospital with 310 beds, staffed by 19 physicians dealing with various specialties. Many social activities, such as schools, club houses, and recreation grounds are also maintained. The president of the company considers that, although the yearly expenditure is large, the health department is, nevertheless, a very profitable investment. Labour turnover has been reduced by two-thirds, lost-time is much less, each day's work is more productive, and the workers (paid by the piece) earn more. There is also more contentment and less friction between labour and management.

# Reports and Analytical Records.

## HYPEROL.

(F. W. Berk and Co., 106, Fenchurch-street, E.C. 3.)

Hyperol is known as solid hydrogen peroxide and is prepared by combining hydrogen peroxide and urea in molecular proportions. It is a white crystalline body with the formula $CO(NH_2)_2H_2O_2$. Its stability at ordinary temperatures renders it of particular use in tropical climates. Hyperol is soluble in water, dissociating rapidly in solution with formation of urea and hydrogen peroxide. When analysed the preparation was found to contain 35 per cent. of hydrogen peroxide as compared with the theoretical 36 per cent. A trace of acidity is present, probably derived from citric acid. As an oxidising agent of high efficiency and purity, hyperol will be of use to the medical man and the chemist.

Hyperol is also supplied in the convenient form of tablets, each one containing 8 gr. of 35 per cent. hydrogen peroxide. On analysis these tablets were found to contain 31 per cent. hydrogen peroxide, a little starch used for binding purposes being also present. These tablets will be found convenient as a source of hydrogen peroxide for toilet purposes and some use.

## NESTLÉ'S CREAM.

(Nestlé's and Anglo-Swiss Condensed Milk Co., 6 and 8, Eastcheap, London, E.C. 3.)

This cream, which is described as "pure thick," was contained in a tin the contents of which weighed 11·5 oz. When analysed it was found to have the composition:—

| | Per cent. |
|---|---|
| Fat .. .. .. .. .. | 27·2 |
| Sugar (lactose hydrate) .. .. | 3·4 |
| Protein .. .. .. .. | 3·8 |
| Ash .. .. .. .. .. | 0·4 |
| Water .. .. .. .. | 65·0 |

The total solids were 35 per cent. and the solids-not-fat 7·6 per cent. No preservatives or thickening agents were found. The cream is thick, homogeneous, and has the slightly cooked flavour which is inseparable from pasteurisation, but this is not masked as in some preparations by the addition of cane sugar. The cream can be described as a pure product and this knowledge will doubtless be of use to the practitioner.

## STAPHAR.

(Dick Coates and Co., 41, Great Tower-street, London, E.C. 1.)

This preparation is well known on the continent and has been the subject of satisfactory communications to the *Deutsche Medizinische Wochenschrift*, among other well-known journals. A staphylococcus vaccine, originally prepared by Prof. Strubel, it is recommended in a great many septic conditions of the skin, some of which have features in common such as sycosis, acne, carbuncles, and boils, and in certain forms of eczema and mastitis. The clinical accounts suggest that the use of the vaccine is free from danger in proper dosage and that in suitable cases injection is followed by prompt subsidence of the symptoms. It is supplied in boxes containing three, five, or ten glass sterilised ampoules of 1 c.cm. each, and these should be well shaken before use in order to obtain a uniform emulsion.

## BISTOVOL.

In a communication on the Chemotherapy of Syphilis, published by Prof. Levaditi in The Lancet of Jan. 30th, reference is made to basic acetyloxyaminophenyl arsinate of bismuth. Messrs. May and Baker, Limited, point out to us that this product, in oil suspension, has been placed on the market by their firm under the registered name of "Bistovol."

been coincident with the recent epidemic of influenza. The authors also quote facts which throw doubt on the old Schneeberg statistics for carcinoma of the lung. The figures given by HARTING and HESSE in 1878 showed that 79 per cent. of all deaths amongst the miners of the Schneeberg district of Saxony were due to this disease. These returns were, however, not adequately checked by post-mortem examinations, and more recent research has shown the *probability that both pneumono*koniosis and tuberculosis were responsible for many of the so called carcinoma deaths. Research work in other quarters seems to indicate that the older authorities not infrequently confused pneumonokoniosis with new growth. Indeed, the whole question of interpreting the older sets of figures is uncommonly difficult Obviously differential diagnosis is of peculiar importance in this disease, and it would be safe to say that more rapid strides have been made on this *aspect of the* subject than on any other. *Radiology* has doubtless played an important part in this advance. Radiograms of the chest increase in diagnostic value year by year, and the *recent introduction of* lipiodol has added yet another weapon to the armament of the radiologist In his introduction to the discussion at the Royal Society of Medicine, Dr. L. S. T. BURRELL [1] stressed also, amongst other diagnostic points, the importance of the absence of tubercle bacilli in the sputum. We are too apt to assume that a negative sputum test means nothing, whereas in point of fact it may mean a good deal. Yet another common pitfall is the Wassermann reaction. More *than once* it has been our experience to see a *diagnosis* of malignant tumour of the thorax withdrawn on receipt of a positive Wassermann reaction report, only *to find* at the autopsy that *malignant* intrathoracic tumour was the correct diagnosis. The possibility of confusion with aneurysm is obvious, but, after all, *there is no reason why a patient with* malignant disease should not have previously had venereal disease ; indeed, it is possible that syphilis may be a *predisposing* cause of malignant lung, as it is of certain other forms of malignant disease. If, therefore, there are good grounds for the diagnosis of the malignant intrathoracic growth, a positive Wassermann test need not necessarily engender doubts of the original diagnosis. Pyrexia and night sweats, too, are frequently misleading signs. All intrathoracic growths sooner or later become septic from retained secretion and not infrequently this complication may effectively obscure the true picture. The association of pulmonary tuberculosis with carcinoma of the lung was emphasised by Dr. BURRELL in the recent discussion ; it constitutes yet another pitfall. Finally, pleural effusion repeatedly recurring after tapping may mask the usual signs of growths. The difficulties of differential diagnosis are, therefore, many and various, and it is small wonder if, in the absence of the newer aids to diagnosis, these cases are sometimes wrongly diagnosed. The importance of early *diagnosis* was emphasised by *more than one* speaker during the discussion. To wait until unequivocal signs of pressure clinch the diagnosis is to wait until all possibility of surgical aid is past. This disease or group of diseases is, in short, a typical xample of the value of the modern method of team ork Laryngologist, pathologist, *radiologist*, and rgeon can all assist the physician and none of them be safely omitted from the team.

[1] THE LANCET, Feb. 27th, p. 423.

having been called to the existence of this fund of material it is likely that, in the near future, more results of pathological investigation will be forthcoming. Thus the group of tumours at present designated sarcoma of the mediastinum offers an especially interesting opportunity for research. By reason of their pressure symptoms they are perhaps more commonly diagnosed during life than are the pulmonary carcinomata, and clinically they form a clearly defined group. From the pathologist's point of view, however, they raise all manner of difficult questions. The histological picture is peculiar, so much so that some pathologists are disinclined to admit that they are true sarcomata. The predilection of these tumours for the middle mediastinal group of glands, the two well-defined paths of extension by the deep and superficial lymphatics of the lung causing markedly different pathological pictures, and the liability to track down the walls of the superior vena cava into the right heart, all add to the diversity of the situation. The pulmonary carcinomata vary in naked-eye appearance to such an extent that it is frequently impossible to decide upon their true nature without careful histological examination. Drs. GROVE and KRAMER, in their article quoted above, enumerate five different varieties—viz., infiltrating, multiple nodular, solitary nodular, miliary, and mixed—with a histological picture of cylinder-celled, squamous, or mixed-cell type. Of these, the miliary is admittedly the most difficult to recognise naked-eye, being liable to be confused at first sight with tuberculosis. The point of origin of these tumours is obscure, and this obscurity is rendered greater by the fact that the specimens are not usually obtained early from the operating theatre, but at the end of the course of the disease, from the post-mortem room, when sequelæ and complications have obscured the picture. There would appear, however, to be some evidence for believing that the majority of these tumours arise from the bronchial mucous membrane. One point worthy of special mention is their not infrequent symbiosis with tuberculosis. In some quarters this symbiosis has been adduced as evidence for the view that tuberculosis is a predisposing cause of carcinoma. There are, however, two other possible explanations—viz., (1) the tubercle bacillus may be a terminal infection as it so frequently is in lymphadenoma, or (2) that carcinoma growing in a lung may readily light up a quiescent tuberculous focus. At any rate, with the extreme liability of the lung to become infected with tuberculosis, it is not surprising that *B. tuberculosis* should be found in association with any other pulmonary lesion. Little can be said concerning the ætiology of these malignant intrathoracic growths. The evidence of the arsenic and cobalt miners of Schneeberg, the suggested relationship between pulmonary carcinoma and the recent influenza epidemics, the after-effects of war gases, and the modern practice of tarring roads, all seem too vague and indefinite to be reckoned with as directly causative factors.

There remains the question of benign intrathoracic growths. Here, again, is a subject for research. Hitherto these cases have been described almost as curiosities; very little is known concerning them, and not being directly fatal they only rarely reach the post-mortem table. Routine radiological examinations of the chest in hospital patients would soon elicit the needed facts as to the prevalence and character of this hitherto little recognised group of diseas

# A CHARGE OF NEGLIGENT DIAGNOSIS: THE JUDGE'S OPINION.

WHEN a medical practitioner is sued in the law courts for damages for some negligence towards a patient, the task of deciding whether he was negligent or not is one for the jury and not for the judge. Experienced judges refrain from expressing their personal views except in cases where the administration of justice will otherwise suffer. Exceptional weight, therefore, attaches to the following opinion delivered by Mr. Justice MCCARDIE in the recent action brought by Mrs. VENN against Dr. J. M. TODESCO and Dr. J. ELDER.

> "I myself have formed the conclusion that upon this evidence before the court these defendants ought not to be found guilty of negligence. I further feel, if one weighs the documents and the whole of the testimony in this case, that if a doctor were to be found guilty of negligence upon such evidence as that before us, then no doctor would be safe."

The learned judge made these striking observations with the knowledge that this was the second of two protracted trials, and that, after a hearing of several days and before the case for the defendants was fully developed, the jury had intimated to him that eleven of them were in favour of a verdict for the defence, while only one was in favour of a verdict for the plaintiff. After this intimation, counsel for the plaintiff having declined to accept a majority verdict, the case proceeded to a finish two days later with the negative result that the jury still disagreed in the same proportion as before. The trial was therefore abortive and the case goes back into the list for yet another hearing. There remains also a point of law to be argued whereon the defendant doctors may be held relieved from liability by virtue of the Public Authorities Protection Act; but there was a hint that the legal authorities are here in conflict and that the point may require decision in the House of Lords. When it is added that the plaintiff Mrs. VENN—for whom in the loss of her husband everyone will feel sympathy—is suing under the Poor Prisoners Rules, and that her solicitor and leading and junior counsel are giving their services without the ordinary reward, the position of Dr. TODESCO and Dr. ELDER is seen to be unenviable. They are put to heavy expense in the necessary defence of their professional reputation, and they will not recover one penny of their costs when they succeed in that endeavour.

The circumstances of the case may be briefly outlined. Mrs. VENN's husband, 60 years of age, was removed to Croydon Borough Hospital on March 18th, 1922, on the advice of his medical attendant, Dr. E. G. D. MILSOM. He had then been suffering for at least three weeks from scarlet fever. It turned out that he suffered from diphtheria as well; at any rate, both those diseases were notified. He gradually made progress towards recovery from them, but on April 26th he underwent an operation for a deep-seated abscess in the hip. Blood poisoning set in and he died on June 15th. Legal proceedings were begun in the following December. His widow complained that there had been negligent delay of between six and seven weeks at the isolation hospital before Dr. R. V. CLARK (the medical superintendent) examined him, and that Dr. TODESCO (resident medical superintendent at the hospital) and Dr. ELDER (then assistant resident medical officer) were negligent in not properly diagnosing the abscess. The claim came before the Lord Chief Justice and a special jury last June. There was a definite verdict in favour of Dr. CLARK, but the jury disagreed, as they have now disagreed again, as to the liability of his two colleagues. Much of the medical history of the case was undisputed; Mr. Justice MCCARDIE commented more than once upon the care and fairness with which the medical evidence was given; the case for the defence was supported, as he observed, with an exceptional quantity of contemporary documents—the admission card with unusual details, the temperature chart with unusual details, and the nurse's reports, while the entries were made at a time when there was no conceivable motive for falsification. The disputed matters were mainly the following. There was an entirely honest doubt whether the information given by Mr. VENN's original adviser, Dr. MILSOM, when the patient was brought to the hospital, really reached the hospital staff. Dr. MILSOM spoke of deep-seated inflammation, but said he never used the word abscess. Mrs. VENN and her son stated that Dr. MILSOM used the word and that the hospital doctors were so informed. Mrs. VENN alleged that her husband's thigh and hip were swollen in great lumps, the inference being that the body was septic at an early stage of his stay in hospital and that the abscess should then have been diagnosed and treated. The hospital doctors' evidence, the nurse's reports, and the temperature chart negatived this; the deceased had attributed pain and tenderness to rheumatism. The case, as already stated, was a charge of diagnosing too late the existence of the abscess, and Mr. JUSTICE MCCARDIE in summing up made some remarks on diagnosis which should be widely read

> "A doctor," he said, "must show and exert towards the patient reasonable skill and reasonable care. In the medical profession, as in other professions, there are men of different gifts—for example, in surgery there is the man who possesses singular powers of insight, great operative capacity, and who gains a world-wide reputation. There is, on the other hand, the man who possesses ordinary gifts, ordinary skill, and the ordinary capacity for care That is the standard that must be applied. .. Difficult though diagnosis is with respect to many matters, there is no matter with respect to which it is so difficult as with regard to a deep-seated abscess ... It is not negligence for one doctor, competent and careful, to form one opinion, and another man, as competent and careful, to form another opinion. In fact, in my view, it is the duty of a medical man .. to form his own opinion honestly and to the best of his ability, and, having formed his opinion, to express it. The professional man who fails in that fails, in my view, in his duty as much as a judge who, having formed an opinion of the case, lacks the courage to express it."

It might be improper to comment upon the evidence in a matter which in a sense is still sub judice, but there can be no objection to repeating the judge's opinion.

◆

# THE STERILISATION OF MENTAL DEFECTIVES.

RECENT correspondence in the *Times* (Jan. 18th and 20th) and a leading article in *Nature* (Feb. 20th) have raised again the question whether it is better to prevent the feeble-minded having children by segregating them under control in institutions or by sterilising them. If the prevention of their reproduction were the only pertinent consideration the advocates of sterilisation have a strong case. It is not clear whether the proposal is to de-sex by castration or simply to prevent reproduction by dividing the vasa or tubes; by either method, however, the desired result is achieved with relatively little trouble and at far less cost than by institutional segregation. But, in fact, we have every reason to believe that to make obvious defectives infertile is only a partial solution of the problem of prevention. "Mental deficiency" is a relative term and difficult, perhaps impossible, to define. But the condition is heritable whether we regard it as a definite character like albinism or as the end term of a series which ranges from clever, through normal and stupid, to a state which is hardly compatible with modern society. Mendelians have satisfied themselves that feeble-mindedness is a unit character and a recessive; Prof. KARL PEARSON concludes that intelligence is a congenital product. Whether the two interpretations are as inconsistent as they may seem at first sight? Whether we are, as appears extremely likely, lumping together a variety of different conditions which are transmitted in ways which are for practical purposes different? What is the position of borderline cases—these and many other questions of the greatest hygienic importance will be left for future solution. Proceeding, however, as we must on what we know rather than on what we do not know, it is really essential that SIR ARBUTHNOT LANE and his colleagues who advocate sterilisation as a "rapid" method of diminishing the numbers of defectives should study further the mode of inheritance of a recessive character.

If the proportion of actual defectives in the population is about 3 per 1000, it is reckoned that about 7 per cent of people will be unsuspected carriers of feeble-mindedness. The mating of two such apparently normal carriers will give one defective child in four, and half the children will again be carriers; one in four will be really normal. If a carrier mates with a normal there will be no defective children but half the family will be carriers. These carriers cannot be identified except by the children they produce with an appropriate mate. Hence the apparent paradox that the proportion of cases of mental defect which are the offspring of actually defective parents is quite small; the majority are the children of people who are apparently quite normal. These facts have been related over and over again; Prof. *RUGGLES GATES puts the case very clearly in his* "Heredity and Eugenics," and it is stated particularly plainly in a letter from Dr. W. M. FELDMAN.[1] Prof. R. C. PUNNETT calculated nearly ten years ago that it would take about 8000 years to reduce the percentage of feeble-minded in the population from 3 per 1000 to 1 in 100,000 by segregating or sterilising those who are themselves feeble-minded. Those who purpose to start any popular movement in favour of sterilisation are in fairness bound to warn the public that they must not expect to see much difference for some time. A character is not necessarily controllable because it is heritable any more than an infectious disease disappears as soon as its parasite is discovered.

But there is no reason why we should not achieve what we can in the way of preventing mental deficiency, and everyone will agree that defectives should not be allowed to breed. The fact, however, that it is only a little which can be done in this way makes one realise that this particular line of attack deals with what is, in a practical world, only a minor part of the whole problem. Those who advocate sterilisation seem to think that nothing but prevention of multiplication is necessary or desirable. But people in general dislike defectives, not because they are apt to produce defectives, but because they are defectives. The village idiot has become repulsive, and hardly anyone will seriously doubt that it is a cruel thing to leave the grosser examples of feeble-mindedness in a world for which they are quite unfitted; it is bad for them and bad for the world, especially for the child world which has not learned what they are. Sterilisation would make them no more fit to be at large; inability to procreate or bear children will not abolish the secondary sexual passions nor will de-sexing save the women from the vileness in every man to which the feeble-minded are such an easy prey. In rougher times defectives were destroyed; they have long been tolerated; the progress of kindliness now requires that they should be taken better care of, and we hope that the county councils will accelerate the provision which is being made for their segregation. Segregation is so desirable that it may be reasonably called necessary; sterilisation is therefore otiose.

# Annotations.

"Ne quid nimis."

## UNIVERSITY REFORM IN LONDON.[1]

FOR those who have and those who have not studied the difficulties to which the University of London has been ever subjected, a volume entitled "University Reform in London," by Mr. T. L. Humberstone, which includes chapters that have already appeared in the *Times*, the *Journal of Education*, and elsewhere, makes interesting reading. For those who have had occasion to watch the various controversies as they developed the book will have its pathetic side, when it is recognised that voluminous discussions, in which men lost their temper as well as the general thread of the debate, can be fairly reduced in a detailed history to a few lines of summary. This is not to say that Mr. Humberstone's story takes the place, for those who want a fully detailed record, of the writings of Sir William Allchin, the reports of various Commissions, and the plenteous serial literature which was topical at the different dates; but this small volume does enable us to see clearly why and how many of the large and bitter divergencies of opinion have arisen.

The attempt to reconcile the ideals of an Imperial examining board with those of a teaching university has been the origin of many schemes during the last 75 years, resulting in proposals for the creation of five or more separate universities, or at any rate of institutions having the right to grant degrees; and all of these various movements have been due to the firm belief of their sponsors that only in their particular way could wisdom be advanced and particular sections of students obtain their best chance. The part that medicine has played in the controversies has been significant, because a faculty of medicine cannot be imagined which takes into consideration only an examining board and not the schools where instruction is given. Again, the fact that, while the metropolis contains a group of the finest medical schools in the world, the university of the metropolis does not offer the students opportunities of graduation comparable to those obtaining elsewhere has needed constant recollection; we may all know the pros and cons of this situation, and how far it has recently undergone modification, without feeling that the inequalities have been removed. The medical aspect of the affairs of London University is not, however, any special feature of Mr. Humberstone's book, though he is clearly aware of the position while discussing the Selborne, the Gresham, and the Haldane Commissions. A particularly interesting chapter makes the complicated episode of the Imperial College of Science and Technology comprehensible, and this is followed by a setting out of the arguments for a single university for London with a summary of recent work under the present charter.

On the vexed question of a central site, Mr. Humberstone has no doubts; he is in favour of the placing of the university on the Bloomsbury site where the area available could be profitably used "for administrative buildings, halls, libraries, headquarters for University societies, and for the Officers' Training Corps, for residential hotels and for numerous social, athletic, and extra-academic purposes, as well as for a group of schools and institutes for research and special subjects, such as a school of law, a school of journalism, a school of military studies, research institutes for comparative pathology and numerous arts, sciences, and professional subjects." The various advantages of the Bloomsbury site are set out presumably as a rejoinder to those who object to this departure, and it is a fair criticism of a valuable piece of work that neither is the formidable nature of the objections dealt with, nor is there any full rejoinder to those who desire to remain in Kensington.

## RESPIRATION AND ANÆSTHESIA.

THE more that the physiology of anæsthesia is studied the more striking becomes the predominance of the part played in the process of narcosis by respiration. Indeed, the physiology of respiration may be said to dominate the physiology of anæsthesia, and all else to be subservient to the part played by the respiratory current and its resultant effects on the composition and the circulation of the blood. The overwhelming part played by respiration in both the induction and the maintenance of inhalation anæsthesia is, or should be, as obvious to the practising anæsthetist as it is to the worker in the physiological laboratory. Nevertheless there has certainly been a tendency for his attention to be drawn too much to other subsidiary phenomena—blood pressure, for example, or the state of the eye—and too little riveted on what is actually the key to the whole problem—the breathing. It is true, of course, that mechanical obstructions to respiration have received due attention, and indeed the importance of evading obstructive swelling and spasm of the upper air passages was a fundamental doctrine of the teaching of the late Sir Frederic Hewitt. The less obvious defects of respiration, however, and their direct influence upon the patient's condition were undetected or little understood, and it is to physiological work that we owe an advance in knowledge of these practically most important matters. When the physiologist and the anæsthetist are allied in work of investigation the results are likely to be both interesting scientifically and valuable in practice. The paper read recently by Prof. M. S. Pembrey in conjunction with Dr. F. E. Shipway is a case in point. Prof. Pembrey's observations on apnœa are enlightening, while his insistence on the rôle of carbon dioxide as the paramount respiratory stimulant is paralleled on the clinical side by cases that Dr. Shipway quotes to show how the breathing may be brought to an end in practice by the free washing out of that gas. Apnœa is most likely to arise during the anæsthesia produced by intratracheal insufflation. Pembrey records a case in which 16 litres of air per minute sufficed to oxygenate the blood, but 30 litres produced apnœa for a period of two minutes. The blood pressure fell during the period of rapid lung ventilation. During the period of apnœa it gradually rose, and as the tension of carbon dioxide in the blood increased the patient began slowly to breathe again. Another form of anæsthesia which may be associated with apnœa is that due to "gas and oxygen" breathed through valves over considerable periods of time. The acapnia which may be thus instituted is shown by pallor, a cold, clammy skin, feeble breathing and a quickened pulse, and is in striking contrast to the full colour, exaggerated respiratory movements, and full pulse that are brought on by the presence of carbon dioxide in excess. Both these types of cyanosis are not uncommonly seen clinically, and their essential difference has to be appreciated by the practical anæsthetist. It is around the function of carbonic acid gas in the lungs and in the blood that the chief recent contributions to the physiology of anæsthesia have arisen. Starting from Haldane's original demonstrations of the significance and relations of the volume of air breathed, workers, among whom are prominent Yandell Henderson, H. W. Haggard, and S. R. Wilson, have arrived at important truths concerning respiration in anæsthesia which had hitherto not been made plain. The practical application of these truths lies in the suggestion that by due use of $CO_2$ in induction the respiration may be so stimulated that with exaggerated ventilation of the lungs a large supply of anæsthetic at the safe concentration may be rapidly inhaled. In this way the concentration of anæsthetic in the nerve centres necessary for anæsthesia may be rapidly and safely reached. The other practical use of $CO_2$ is at the close of anæsthesia when again, by inducing vigorous respiration, the anæsthetic may be rapidly washed out of the blood and lungs, and recovery be expedited with consequent diminution of after-effects. With regard to the first of these two practical propositions there is an objection that arises in practice which is not apparent in the laboratory. This depends on the sensations of the patient. Anyone who has experienced the sensation of entering anæsthesia with nitrous oxide or with ether through the medium of forced breathing will assert that he has no desire to repeat the experience. There is no doubt that the physiological method is safe and certain, but it is extremely uncomfortable as compared with a more gradual induction. Moreover, although so far with ether it has appeared safe, there is the general principle to be borne in mind that sudden changes of bodily conditions are, generally speaking, inadvisable as compared with gradual changes. Medicine provides numerous examples which show that a particular condition may be harmless if gradually reached, dangerous if suddenly instituted; and it is not unlikely that anæsthesia complies with this general rule. So far as we are aware the experiment has not been made of rushing a patient into chloroform anæsthesia by exaggerated inhalation of a safe percentage vapour, and we are inclined to doubt the wisdom of making the experiment. The value of forced breathing to rid the body of the inhaled anæsthetic is another matter and appears to be a most valuable addition to the anæsthetist's powers to avoid deleterious results from his administration. It is obvious that so efficient a weapon as carbon dioxide needs careful handling, and scrupulous control must be exercised of the percentage vapour administered after anæsthesia. The proper percentage in oxygen appears to be about 7. The disadvantage of employing the obvious and most simple means of supplying $CO_2$—namely, by making the patient re-breathe his own expirations—is that these must contain a considerable amount of the very anæsthetic vapour which is to be expelled. The necessity for carrying yet another cumbrous cylinder, containing the required percentage of $CO_2$ in oxygen, may be avoided, as Dr. I. W. Magill has pointed out in our columns, by the use of sparklet bulbs.

## RATE-AIDED HOSPITALS.

Some remarkably interesting particulars of the extent to which hospital accommodation is provided or aided by local authorities were recently given by the Minister of Health in answer to a Parliamentary question. Mr. Chamberlain stated that there is only one large general hospital provided by a local authority. He did not mention its name, but he was obviously referring to the City of Bradford Municipal General Hospital, with its 750 beds. Add to this three relatively small accident hospitals and the number of general institutions so provided is exhausted. There is no official information on the number of cases in which voluntary hospitals are municipally aided apart from services rendered to the municipality, but before long they will probably reach a respectable total. By last year's Public Health Act, which has been in operation only six months, local authorities have power to help voluntary hospitals to the extent of a penny rate, but it has as yet been very little exercised. Municipal hospital activities of a statutory character have now become very extensive. Thus, there are 158 tuberculosis hospitals with nearly 11,000 beds; 1010 hospitals for acute infectious diseases with approximately 37,700 beds; 68 maternity institutions with 908 beds, not including maternity wards in general and Poor-law hospitals; and a dozen babies' hospitals with 200 beds. The tens of thousands of beds in the infectious diseases hospitals include 2230 for the treatment of tuberculosis. A large number of voluntary hospitals receive payments from the rates in return for services rendered in connexion with tuberculosis, venereal diseases, maternity, and child welfare schemes. For tuberculosis there are 153, and for venereal diseases 130 hospitals which provide beds as and when they are required, and for maternity and child welfare a dozen hospitals provide 175 beds. In this category there are 127 special tuberculosis hospitals with 8563 beds, 52 maternity institutions with 917 beds, and 12 babies' hospitals with 334 beds. These figures are exclusive of accommodation in homes for unmarried mothers and their babies, observation wards in connexion with maternity and child welfare schemes, and convalescent homes. The Poor-law authorities provide 64 institutions, with 35,250 beds, wholly for the sick, exclusive of institutions for mental cases, and 590 mixed institutions capable of housing 180,000 persons, with 79,000 beds for the sick. If, and when, the councils take over the functions of the boards of guardians, they will thus receive an enormous addition to their public health responsibilities. Meanwhile, these figures add greatly to the strength of the case for the coördination of official health services.

## A GERMAN VIEW OF NICOTINE.

The third and fourth parts of the seventh volume of "Ergebnisse der gesamten Medizin,"[1] which is appearing in instalments under the general direction of Prof. T Brugsch, contain articles on subjects as diverse as the diagnosis and treatment of cancer, the radiological diagnosis of gastric and duodenal ulcers, ankylostomiasis, tetany, the nervous child, suggestion and auto-suggestion, and the adrenal blood reactions. In an article on Nicotinism Prof. Heinrich Kionka presents a summary of existing knowledge on the effects of tobacco and their treatment. Nicotine, he states, exists in tobacco in quantity varying from 1 to 8 8 per cent, while in France, where the plants are set wide apart, the percentage may reach 6. Few people, he thinks, realise what a deadly poison this alkaloid is; one drop of the fluid preparation is fatal to a dog and nearly so to a man. Its action on the nerve centres is violent stimulation quickly followed by paralysis; function is accelerated for the time, and unstriped muscle is stimulated by the over-secretion of adrenalin. It is partly this tonic effect that makes tobacco so universally desired, and partly the assistance which it gives to digestion by making all the glands secrete more copiously. The sedative effect he attributes to carbon monoxide rather than to nicotine. This, it is stated, is present in tobacco-smoke in startling quantities, and is the real cause of most of the symptoms of the non-smoker who feels unwell when surrounded by eager devotees in a railway compartment or unventilated room. The reason why nicotine does not do more harm amongst smokers is, of course, that tolerance is easily acquired, and though the beginner shows signs of poisoning at once, he soon becomes immune. Nevertheless, the limits of this tolerance are easily passed, and, according to Prof. Kionka, the inveterate smoker who oversteps the mark suffers far more than the beginner, for his tissues are more or less saturated and he has less resilience. The quantity of nicotine present in tobacco-smoke varies considerably. The content in the leaf is said to be unexpectedly independent of the strength of the tobacco. Whereas with Dixon's apparatus 100 g. of light cigars gave up 1000 mg. of nicotine, compared with 480 mg. yielded by the same weight of strong cigars, two German brands of so-called nicotine-free cigars gave 420 and 320 mg. respectively. The quantity the smoker actually absorbs varies with the capacity of the cigar, cigarette, or pipe for distilling and trapping the nicotine from the burning tobacco. A long pipe is better than a short one, a dry cigar than a damp one, and the first half of any smoke does much less harm than the last. The cigarette, says Prof. Kionka, is the worst of all, for its paper covering collects the products of distillation, which are revapourised and absorbed as the cigarette burns down to the end. The smoker who re-lights a pipe or cigar, it is stated, probably absorbs more poison than he would from ten straightforward smokes, whilst chewing and snuff-taking are regarded as not nearly so harmful as smoking, because only a little nicotine is absorbed. There is hardly a single pathological condition, Prof. Kionka says, that tobacco cannot cause or aggravate. It sets up sclerotic and necrotic changes in the heart and large vessels, causes colour-blindness and scotoma, damages the hearing by causing swelling and congestion in the inner ear, and, in specially disposed subjects, will produce a toxic psychosis or any of the minor psychic and nervous troubles that go with cumulative poisoning of the sympathetic system. Like all other habit-forming drugs, he continues, it produces worse effects when it is a psychological factor. The ordinary man smokes because he likes it and cuts down his consumption when he has the familiar symptoms of over-smoking, but the nervous man who uses it to tone his nerves up for brain-work, when he should have learned to control them otherwise, may find himself in a bad way. Provided the poisoning has not continued so long that there are organic changes, says Prof. Kionka, the damage in all cases of chronic nicotinism is largely reparable by stopping all tobacco and purging the system by a course of exercise, baths, and medicine. Iodide of potash is also useful. If nicotine is harmful to adults, he concludes, it is deadly to adolescents, and most civilised countries enforce stringent laws against smoking by young people.

## THE HEALTH OF THE MAORI.

Last year a series of articles appeared in the *Evening Post* of Wellington, New Zealand, on various aspects of public health activities. These attracted some attention, and the Dominion Department of Health decided to republish them in booklet form under the title of " Striking Facts and Figures " for the information of the general public. The articles are a form of official propaganda and fulfil this purpose well, although unsigned. New Zealand does not appear to admit the claim that to be attractive to the public an article on health must be signed with a famous name. The health of New Zealand has of recent years frequently been held up as an example to other nations. Of the health of the native population little is heard, and it might, perhaps, be thought that this was not so much a subject for pride. Such an idea is, however, shown to be erroneous by the final article which treats of Maori hygiene. Although at first in the hands of the Native Department, in 1901 certain important changes took place, and amongst them was the appointment of Dr. (now Sir Maui) Pomare, the first native graduate in medicine, as medical officer of health under the Health Department. He set in motion at once sanitary reforms among the Maori population which have negatived the pessimistic prediction of the extinction of this fine race. Soon after Dr. Pomare's appointment nine Maori sanitary inspectors began their work, and in 1905 another Maori health officer, Dr. Te Rangi Hiroa, was appointed to assist Dr. Pomare. There are now over 20 native health nurses at work in the more populous Maori districts, lecturing to the women on the feeding of infants, the care of the sick, and other practical matters. Pamphlets in the native language have been prepared on the feeding of infants, tuberculosis, typhoid, influenza, scabies, among other subjects, and there is a good demand for them. Not mentioned in the booklet is the remarkably low death-rate from cancer among the Maori community discovered by Mr. J. W. Butcher in a statistical study to which attention will later be called. Linked up with preventive work is a certain amount of anthropological research. The social and physical improvement that has taken place since 1900 is attributed to the various measures thus briefly set out. Sir Maui Pomare is now Minister of Health in the New Zealand cabinet, Dr. Hiroa is director of Maori hygiene, and the rescue from extinction of one of the finest races in the world substantiates New Zealand's claim to have a sensitive health conscience.

## THE PREVENTION OF POST-MORTEM INFECTIONS.

We have been sadly reminded in the opening weeks of this year that post-mortem examinations are not without risk to those engaged in this branch of professional work, for two pathologists have recently died as the direct result of infected fingers due to minor injuries received in the course of a routine autopsy. The gravity of the position cannot be correctly gauged from sensational headlines of the lay press in such cases, nor does it seem possible at the moment to arrive at accurate statistical information of the incidence of infections following post-mortem examinations. The Registrar-General rarely reports more than one death per million in any year from all the injuries due to cutting or piercing instruments. In view of the very large number of autopsies performed annually, there can be little doubt that disaster follows in an extremely small proportion of cases. Indeed, this is so well recognised in the profession that a feeling of false security is engendered, and small injuries are regarded of no moment. Even if the accident is recognised as potentially serious, there seems to be uncertainty as to what prophylactic measures should be adopted. Among those who work in the pathological departments of the big metropolitan and provincial hospitals familiarity is apt to breed contempt, and often insufficient care is taken to provide facilities for protection and for prompt and adequate treatment. Moreover, any medical man in practice is liable to be called on to perform an autopsy, though he may have but little experience in the technique. Therefore, we commend to the serious attention of all our readers the analysis of the causes of post-mortem injuries and advice as to their prevention, which forms the subject of this week's article in the Modern Technique in Treatment series.

## MORBID CHANGES IN PELLAGRA.

Opportunities for the careful post-mortem examination of the subjects of pellagra are rare in this country. Such an opportunity in the shape of the death of two patients, one suffering from undoubted pellagra and the second a probable case, presenting itself at the Royal Hospital, Edinburgh, has enabled Dr. William Susman, working with a Hoffman Scholarship from the Queen's University, Canada, to make a very full and complete report[1] upon the pathological changes in this condition. Dr. Susman finds the oldest and most pronounced lesions in the thyroid gland which shows proliferation of the vesicular epithelium into the vesicles together with fibrosis and a generalised round-celled infiltration, indicating the spread of a toxic product by the lymphatics. Other organs also showing evidence of irritation by some toxic product are the liver, kidneys, and pancreas. The liver is markedly affected, the irritative process resulting in a fibrosis. In the pancreas the degenerative process affects principally the zymogen cells; the islets of Langerhans are numerous and large, and the cells contain many alpha granules; many of the islets give evidence of damage in the shape of hæmorrhages. The kidneys show peritubular degeneration and fibrosis which, in the opinion of the author, indicates that the causative toxic product is excreted through these organs. The spinal cord shows a degeneration of the dorso-spino-cerebellar tract of a type similar to that described some years ago by Batten and Sandwith. Examination of the fæces by section failed to reveal the presence of amœbæ and presumably, since no mention is made of them, of all other varieties of protozoan parasites. No suggestions as to the origin or nature of the toxic product giving rise to the lesions described are hazarded by the author.

## AN INSTITUTE OF BIOCHEMISTRY AT THE MIDDLESEX HOSPITAL.

Mr. S. A. Courtauld has given £30,000 to the Middlesex Hospital for the erection, in connexion with the medical school, of the Courtauld Institute of Biochemistry, and the plans provide for a new seven-storey building to be erected on a site adjacent to the premises of the medical school. The Institute is designed to be a complete department of medical chemistry, where the most recent methods in diagnosis can be considered for application to the patients of the hospital, while the research work will be directed to the elucidation of problems in physiological and pathological chemistry, and the preparation of chemical substances which suggest themselves of value in treatment. Full facilities will be provided for the instruction of students in biochemistry. The new Institute will work in close association with the Bland-Sutton Institute of Pathology. In 1921 Mr. Courtauld endowed the Chair of Anatomy at the Middlesex Hospital Medical School with a sum of £20,000, so that his gifts for medical education and research, apart from donations for hospital maintenance and reconstruction, amount to £50,000. His latest gift is a striking illustration of breadth of vision, for the possible developments of biochemistry as the ally of medicine are of the utmost promise. Clinical medicine is continually annexing subsidiary sciences to help in the elucidation of its problems. The first was anatomy, normal and morbid, the science of direct observation of the gross structure of the body. This was followed by the study of function in health and disease, and still later the fruits of microscopical observation were enlisted. To-day exact information as to the chemistry, not only of natural products but of physiological and pathological processes, is felt to be the great need of modern medicine. Biochemistry has become so wide as to need subdivision, with the result that while some laboratories work only on abstract problems with no direct clinical or commercial application, others are devoted to the study of physiological processes. A comparatively small body of workers in this country are attacking the clinical applications of biochemistry, and these for the most part are clinicians with special scientific attainments rather than chemists profoundly interested in medicine. Mr. Courtauld's generous gift is intended to found an Institute embracing all branches of biochemistry, but with a general trend towards the study of clinical conditions. Since the new Institute will be responsible for all the chemical routine work of the hospital, the workers will be in intimate touch with the patients. Under the direction of Prof. E. C. Dodds there is little fear that the therapeutic aspect of the work will be neglected, for he has long given practical proofs of his interest in the clinical application of his researches. All branches of biochemistry will be studied in the new Institute—the pure chemistry of natural products, physiological and pathological chemistry, together with the routine work. In addition to clinical facilities, the workers will have the benefit of collaboration with the Bland-Sutton Institute of Pathology, and it is proposed that chemotherapeutic researches shall be started by the two departments working in close association.

---

KING EDWARD'S HOSPITAL FUND FOR LONDON.—Hospitals desiring to receive grants from this Fund for 1926 must make application before March 31st to the hon. secretaries of the Fund, 7, Walbrook, E.C. 1. Such hospitals must be in the county of London or within 11 miles of St. Paul's. Applications will also be considered from convalescent homes which are situated within these boundaries or which take a large proportion of patients from London.

---

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXIV.—THE TREATMENT OF POST-MORTEM INFECTIONS.

POST-MORTEM injuries are usually trivial; it is rarely that a wound of any considerable size is seen. They may be punctures, scratches, or incised wounds, and occur most frequently in the terminal segments of the left index and middle finger, and on the ulnar border and the posterior surface of the forearms and hands. It is instructive to analyse how these post-mortem injuries usually occur.

The *puncture wounds* of the left index and middle fingers may be produced by a prick of the knife point, and appear to happen principally during (1) the removal of the tongue and fauces from the mouth through the mid-line incision in the neck; (2) the mobilisation of the liver and its separation from the diaphragm; (3) the en bloc removal of the contents of the pelvis. They may occur also during the investigation of some morbid condition involving bone—e.g., an aneurysm of the arch of the aorta eroding the bodies of the dorsal vertebræ, a chronic bone infection, or a growth of bone. Small spicules may be lying loose in a cavity or may project from the surface, and being unpleasantly sharp may have punctured the finger before any danger is anticipated. Similarly, the finger may be pricked by the jagged edges of carious teeth.

There is another way in which the knife may cause trouble. While the viscera are still in situ but exposed, an occasion sometimes arises when both hands are needed (e.g., the stripping of an adherent pleura to mobilise the lung) and the knife is placed, not on the table, but among the intestines, between the coils of which it sinks to ambush. Later comes the exploration of the abdominal contents and the knife recalls its existence by stabbing the examining finger. Few pathologists will admit that they have been guilty of such wanton carelessness, but many declare that they have seen other workers lose sight of a knife in this way.

Pricks from needles are rarely seen among post-mortem workers, who use needles almost exclusively for suturing the skin incision, and employ large, easily handled ones. Yet I am informed that pricks of the two fingers do occur, possibly because by that time the interest of the case has lapsed, and the suturing is an irksome task to be completed as soon as may be. The post-mortem operator—unlike his surgical colleague—does not use dissecting forceps to assist his suturing, but steadies the skin with the fingers of his left hand, and it is thus easy to understand how a tired worker may inadvertently prick his finger. A curious example of needle injury, from which no untoward consequence resulted, is that suffered by a pathologist during an autopsy on a man who had died on the operating table. Amongst other restoratives applied had been direct injection of a stimulant into the heart, during which process the needle was snapped off short in the body; at the autopsy the pathologist pricked his finger on the buried fragment.

*Scratches* are produced mainly in one way. The thorax cavity is exposed by dividing the costal cartilages on each side near the costo-chondral junction, or the ribs are sawn through further out. Often adherent lungs demand the introduction of the hand and forearm into the thoracic cavity, and it is during this manœuvre that the skin is liable to be scratched by the projecting ribs or rib cartilages.

*Incised wounds* by the knife are rare and can generally be avoided by the experienced worker.

*Surgical Injuries.*—Injuries received during the course of a surgical operation are in many ways similar to the post-mortem ones. They are inflicted by knives, needles, and bone spicules, and are probably far commoner than in the post-mortem room, but so many operation cases are "clean" ones, and the surgeon's hands have been so thoroughly prepared, that the probabilities of infections following are greatly diminished. Nevertheless, they should be treated with the same respect, and the whole process of prophylactic treatment gone through, for it is not always possible to decide when an operation case is infected or not.

*Bacteriology.*—The vast majority of causative organisms in these conditions are the pyogenic cocci. Theoretically there are many others, but actually few cases will be seen that are the result of anything but staphylococci or streptococci, and of these the latter is infinitely the more serious. The fulminating types of lymphangitis are a virulent streptococcal infection, and though a staphylococcus may give widespread and dangerous trouble locally, it rarely gives a septicæmia unless the treatment has been grossly at fault. It is worth taking a swab when a septic finger or hand is opened, for it does help to form some idea of the prognosis of the case, and, moreover, an autogenous vaccine may be prepared for use if it is thought desirable.

### *The Prevention of Injury.*

Methods of preventing accidental injuries fall into three groups: (1) adequate protection, (2) proper technique, and (3) reasonable care.

*Adequate protection* is essentially a matter of suitable clothing. Even in big institutions protection is often insufficient, and among those who do only occasional autopsies the main idea often is to safeguard the clothes and not the skin. The proper apparel is as follows: First a mackintosh; over this a long-sleeved overall with elastic bands at the cuffs. The ordinary type of operating gown serves admirably, and, in fact, in many hospitals pathologists' overalls are made to the same pattern, but of a different coloured material to avoid confusion at the laundry. Next, gloves must be worn; a totally unjustifiable risk is run if they are omitted. They should be of the gauntlet type, and the best variety is that which combines fine roughened hands with coarse rubber for the forearm extension, which should reach nearly to the elbow; further, the cuffs of the gown must fit snugly to the gloves at the wrist. A pair of cotton gloves over the rubber ones are useful protectives, for surgery on the living has taught us how consistently these deflect spicules of bone and so prevent the perforation of the rubber beneath. In this way the sense of touch is not too seriously impaired, while adequate protection is ensured.

*Technique.*—The surgeon develops a well-devised technique from long experience, his main object being to preserve the safety of the patient. The post-mortem subject having passed beyond the need of such care, the operator should consider his own safety. It would be out of place here to dwell on the methods of conducting a post-mortem examination, and I will consider the technique only as far as the handling of instruments is concerned. Surgeons visiting the post-mortem room are often amazed at the casual way of the pathologist with his instruments. These are usually to be seen on the table beside the body, probably to end by slithering into the groove between table and body, where in due course they will be covered by some of the removed viscera. Attention has already been directed to the habit of laying knives on the body. As so very few instruments are needed a very simple working scheme should suffice. A small table, comparable to a bed table, astride the body, with sufficient clearance to avoid the thighs, might be used for instruments. Similarly, during the examination of the removed viscera an instrument tray should be used. Mention has been made of the part played by the divided ribs or costal cartilages in scratching hands and forearms. The method usually adopted is to fold the musculo-cutaneous flap raised from the sternum and chest wall over the projecting ribs so that these are hidden from view. It seems that in many cases the division of the costal cartilages cramps the worker for room rather seriously, and it would probably be much wiser to saw the ribs through further out as a routine procedure. Lastly, to avoid needle pricks during sewing up, dissecting forceps should be used. It may be said that to those without constant practice suturing already takes a long time; but after all, the pathologist has only to sew up reasonably neatly and he need not bother about accurate co-aptation or inversion of the edges. In most big hospitals the skin suture is done by the post-mortem attendant with dexterity and speed, but without great care. These unqualified assistants are specially apt to hurry through this work; the use of dissecting forceps should be taught and practised as a routine measure by everyone in the pathological department.

*Reasonable Care.*—It is in the absence of a living patient who will suffer from error that carelessness is so apt to take root, and it is often the man with a fair amount of experience who errs the most—the novice being far too anxiously concentrated on the work in hand. We have all seen the reflection of the musculo-cutaneous flap continued with bold sweeps of a knife while the manipulator looks aside to answer questions or to dictate notes. The subject may be beyond injury, but the pathologist's fingers are not. Incidentally the clinical honorary staff are sometimes guilty of urging the performance of an autopsy at an unusual time when the pathologist has other duties, or of attempting to hurry the progress of a dull case belonging to someone else in order to witness the examination of a supremely interesting one of their own. The code of the operating theatre or, indeed, of the navigation bridge, might with advantage be more closely followed in the post-mortem room. Some pathologists aver that as time goes on they and their assistants probably develop a natural immunity, and it has even been suggested that those who get slight septic infections in their early days of post-mortem work are fortunate in that they are raising an effective barrier against later and possibly more serious trouble. This is an attractive theory, but is hardly susceptible of proof, and few would recommend attempts to immunise beginners in this dangerous way.

### *The Prophylactic Treatment of an Injury.*

The problem before us is the selection of the exact procedure to be adopted when a finger is pricked or cut or the forearm is scratched during post-mortem work. The desirability of the immediate adoption of such drastic measures as amputation or excision of the wound have recently been discussed. I find it difficult to choose words emphatic enough to condemn panic amputation. If we consider how small is the number of severe infections following post-mortem injuries and how rarely does a fatal issue follow or a serious deformity result, we must conclude that hasty amputation, which must bring with it great disability, is never justifiable. Such advice would imply that an infected finger means probable death or disablement, for on no other grounds could a crippling operation be justified. Fatalities may result either from the fulminating type of lymphangitis—fortunately rare—or because the early treatment of the infected finger is inadequate, but their occasional incidence should not be allowed to induce such a pessimistic outlook as to interfere with a sense of proportion.

The question of the excision of the wound has also been raised. I do not advise excision for the following reasons. Needle pricks and knife punctures are very small and, in fact, can often not be recognised unless bleeding, and the area in question may therefore be too ill-defined to excise. Secondly, the pulp of the finger has none too much tissue to spare; if excision were performed, a painful scar in the tactile part of the finger would often result. In the presence of scratches of the superficial epidermis, to think of an excision, which entails the opening up of the subcutaneous tissue and often an extensive sutured wound, is surely inadmissible. When the wound is an incised one of some size and depth on the forearm or the dorsum of the hand, then I have nothing to say against excision, except that I consider it unnecessarily severe, for it must be remembered that post-mortem wounds of this sort are regular incised wounds without any severe laceration or damage to the underlying tissues. The problem is not quite the same as that of the war injuries, where we had to deal with damaged and devitalised muscle which directly encouraged sepsis. Finally, I believe that post-mortem injuries can be effectively sterilised without such drastic methods.

The steps to be taken in these cases are as follows: (1) cease work at once; (2) encourage bleeding; (3) cleanse the wound thoroughly; (4) immerse the wound in an iodine bath; (5) put on a sterile dressing; (6) give suitable drugs; (7) immobilise the arm.

1. *Cease work* obviously means that work should be instantaneously abandoned and handed over to someone else; should there be no one available the whole routine of the treatment should be gone through (except immobilisation), and the examination finished as quickly as possible, with a fresh glove over the injured part.

2. *Encourage Bleeding.*—Generally the immediate concern of the subject of the injury and of the onlookers is to stop the bleeding. This instinct is not to be followed. Bleeding—especially slow welling-up from the depth of the wound—will wash out infecting organisms quicker than anything else. The wound, if not bleeding, must be made to bleed, and the best way to do this is to use the arm compressor of a sphygmomanometer and to blow it up till passive congestion is obtained. If it is blown up until the radial pulse disappears and air released until the pulse is again perceptible, the right amount of pressure will have been secured. The bleeding should be allowed to continue for two and a half minutes by the clock and then, the arm band having been removed, the next stage should be proceeded with.

3. *Thorough Cleansing of the Wound.*—When discussing the treatment of injuries to the hands of industrial workers I have always deprecated washing or scrubbing the part, for this reason. Their hands, from the nature of their work, are very dirty, and scrubbing only means the introduction of more dirt into the wound; the hands of post-mortem workers may be stained with dyes but are otherwise clean, and there is a minimum of infection around the wound. These injured fingers or hands should therefore be scrubbed with a sterile nail-brush and ether soap. The part is then dried with a clean towel and immersed in the iodine bath.

4. *Iodine Bath.*—By this I do not mean the usual drachm to the pint solution used in the treatment of established infections, but that the injured part must be *immersed* in an alcoholic tincture of iodine and kept there for *five* minutes by the clock. The edges must be separated so that the iodine penetrates to the depths. The evidence in favour of iodine as a prophylactic is overwhelming as the statistics of Kanavel and of Mock show. Its value is proved by its use in thousands of industrial concerns all the world over, and it is one of the components of the army first field dressing. But it must be used properly and lavishly. I know nothing more futile than the custom of dabbing a small amount of tincture of iodine on to a cut with a swab.

5. *The Sterile Dressing.*—A sterile or antiseptic dressing is now applied with a generous amount of wool, and the greatest care must be taken to ensure that the bandage is not so tight as to impede the flow of blood through the injured area.

6. *Drugs.*—Of the value of manganese I am convinced. Manganese butyrate should be given in 1 per cent. solution as a 1 c.cm. injection into the muscles of the buttock. Prof. L. S. Dudgeon reports favourably (see THE LANCET, Jan. 23rd, p. 169) on the intravenous use of mercurochrome.

7. *Immobilisation of the Arm.*—The value of the immobilisation of an injured area to allow the natural defences of the body full scope for their efforts to localise the infection is obvious. The arm should be placed on an internal angular splint which must reach beyond the tips of the fingers and is comfortably fixed with wool and bandages. The remainder of the day ought to be spent quietly at home and to be followed by a long night in bed. The splint may be removed on the next day and the hand carried in a sling till 36 hours have elapsed. Finally, if the least swelling, throbbing, or pain at the site of injury occur a surgical opinion should be obtained without delay.

### *Treatment of an Established Infection.*

It may be that a prick is so slight as to have escaped notice, or that infection has supervened in spite of energetic prophylaxis. In an article on Infections of the Hand, which previously appeared in this series,[1] I have summarised the differential diagnosis and treatment of the various forms of sepsis that may arise from injuries to the finger. Briefly, to recapitulate, the inflammatory process may take the following forms (1) acute lymphangitis; (2) infection of the terminal segment of the fingers; (3) acute tenosynovitis, and (4) infection of the fascial spaces in the palm

The treatment of septic conditions other than lymphangitis resolves itself into proper incision and drainage; when this is adequate healing results, when it is neglected nothing else can help the patient. Whereas lymphangitis is at first an infection of a few lymphatic vessels and tends to remain localised, spreading only by continuity up these normal paths, if the area is incised numbers of healthy lymphatics are opened up and infected, the total area of inflammation being vastly increased. For the same reason cuts across the advancing red lines are to be condemned. For these reasons, though differential diagnosis between all these conditions named is of great importance, the first and fundamental distinction to be made is that between acute lymphangitis and any of the others. I will therefore first briefly recall the principles of the differential diagnosis and treatment of the septic conditions other than lymphangitis and then discuss at greater length the best ways of coping with this dangerous condition.

1. *Infection of the Terminal Segment of the Finger.*—A sensation of soreness, possibly of pricking in the finger-end, and that night a throbbing pain of increasing severity, is a common history. On the following morning there is a red, tense, shining, very swollen and tender finger-end. There is an absence of severe constitutional symptoms, and of typical red lines in the forearm. Treatment should consist in one or, if necessary, two lateral incisions, or a horse-shoe incision formed by uniting the two lateral cuts, which should not extend upwards as far as the distal finger crease, by one over the tip of the finger, a quarter of an inch in front of the nail.

2. *Infection of the tendon sheath* can arise (*a*) directly from a gross crushing injury, (*b*) following on a pulp infection. The latter only need concern us here. Kanavel gives as the cardinal signs of infection of the tendon sheath: (1) Exquisite tenderness over the entire course of the sheath. (2) Symmetrical enlargement of the entire finger. (3) Excruciating pain on complete extension of the finger, most marked at the proximal end. (4) Moderate flexion of the finger. In addition the bases of the two adjacent fingers are swollen, and the dorsum of the hand is highly œdematous. The whole hand is somewhat tender, but even the slightest pressure over the sheath gives intolerable pain. The trouble may extend to the bursæ in infections of the little finger and the thumb. A raised temperature and rigors may be present, but the local signs will serve to distinguish the infection from primary acute lymphangitis. Treatment consists in lateral incisions of which the exact position, extent, and direction cannot here be defined, but it may be said that they are more often too small than too large.

3. *Infection of the Fascial Spaces of the Palm.*—Fascial space abscesses are usually secondary to infection elsewhere in the hand. The temperature is likely to be high and the general condition bad. Pain over the area, not so accurately limited as in acute tenosynovitis, tenderness, and local swelling, are present. In infection of the middle palmar space the dense fascia does not allow of much swelling, but the normal concavity of the palm may be rendered convex. Treatment is the drainage of the spaces through

---

[1] THE LANCET, 1924, i., 960.

the canals of the appropriate lumbrical muscles, the incisions extending from the web, distally, as far as the middle flexion crease, but not beyond.

4. *Pus Spreading to the Forearm.*—Pus may track from hand to forearm either by rupturing out of the upper limits of the synovial bursæ or along the upward prolongation of the middle palmar space. The result is the same, for both routes lead to the plane between the superficial flexor mass and the deep flexors with the pronator quadratus. From here pus can track laterally to reach the ulnar and radial borders of the forearm immediately anterior to the bones, or upwards along the same plane towards the elbow. It is therefore clear that the only method of draining such an extension is by lateral incisions parallel to and immediately anterior to the plane of the bones. Severe cases will demand an incision on each lateral border; no other approach provides adequate drainage.

The brief statements as to treatment must not be taken to imply more than the general lines which a surgeon of experience will follow. In the article already referred to I have given more details, but those who wish to equip themselves to treat infections of the finger and hand are advised to study Prof. A. B. Kanavel's masterly work on the subject.[2] I would here only point out the need of a general anæsthetic (gas and oxygen) for every operation; the desirability of operating in a bloodless area, using the arm compressor of a sphygmomanometer first as a tourniquet and later to induce passive congestion; and the advantages of using wicks of rubber tissue for drainage. No incision should be made before the exact anatomical position of the pus has been determined, and though swelling of the dorsum of the hand may be, and usually is, prominent, incisions should not be made there until every other possible site has been excluded. After-treatment should consist of fomentation for 72 hours, followed by light dry dressings and hot, dry air baths. Early active movements of the fingers should be encouraged.

### *Acute Lymphangitis.*

It is this dangerous condition which, from the very fact that no drastic surgical treatment is called for, gives rise to some of the most perplexing problems of therapeutics. It is essentially an infection of the lymphatics, with little or no extra lymphatic local infection at the primary site, though at a later date a local abscess may form at the site of infection. The process spreads rapidly through the normal lymphatic channels up the forearm, into the axillary glands, and later in severe cases into the general blood stream. A slight injury to a finger may be followed by a slight feeling of tense discomfort without the typical throbbing of an infected pulp; on examination there is no appreciable local swelling. A feeling of chill or even occasionally a rigor may have occurred. The red lines of lymphangitis will be visible in the forearm and grave constitutional symptoms will be present. Kanavel has described four types of acute lymphangitis:—

1. Acute lymphangitis, without local complications. Here the symptoms are as described above with red lines and a temperature of 103° F., and a general feeling of severe malaise. Treatment produces a dramatic change, and within a few hours the condition is relieved. (2) A similar condition which clears up quickly, but leaves behind a small local abscess at the site of infection. (3) Acute lymphangitis, with systemic involvement and associated with severe secondary tendon-sheath infections. (4) Acute lymphangitis, with severe systemic involvement.

These last may be of the fulminating type, rapidly flooding the patient with an acute septicæmia followed by a fatal result in a few hours or days. These cases constitute one of the tragic disasters of surgery. Other cases, though not fatal, exercise the skill, patience, and lasting power of the medical attendant to the utmost. They rapidly become seriously ill with a maintained high temperature, rigors, wasting, and a reduction of resistance to the lowest ebb; but with energetic treatment they will mostly pull through.

The treatment of acute lymphangitis must be local and general. The local treatment consists in swathing the hand, forearm, and arm in an old-fashioned poultice, for fomentations lose their heat too rapidly. Only in the presence of well-defined complications, such as localised abscesses or tenosynovitis, is active surgical intervention called for. It cannot be too strongly emphasised that incisions for lymphangitis do no good. Indeed, as is pointed out above, they do harm in increasing the area for absorption.

The general treatment is confined to eliminative and supportive methods. Absolute rest and quiet, saline purgatives, diuretics, and stimulants all have their place. Antistreptococcal serum in large doses has been used without very encouraging results. However, I have found blood transfusion a weapon of the utmost value in combating septicæmia, and recommend that the grouping of available donors should be undertaken at the first threat of a serious infection, one being kept always at hand till the acute stage is past. Metastatic collections of pus must be watched for and the danger of an empyema borne in mind

Assistant Director, Surgical Unit, St. Mary's Hospital.

# Special Articles.

## LIVERPOOL CANCER RESEARCH COMMITTEE.

THE following memorandum has been sent to THE LANCET for publication:—

It may be held to be wise to ignore criticisms that have no basis in fact. Nevertheless, the spread of adverse criticism creates rumours, and from our war-time experience we know how damaging rumour may be both to morale and to the pursuit of proper procedures. For this reason we consider it expedient to inform the medical profession of the truth of certain matters concerning which grave and unjustifiable charges have been made. These charges are of two kinds.

1. It has been stated that some great secret has been withheld from publication—that is to say, the method of preparation of the material used has not been disclosed. Now, in spite of the fact that Prof. Blair Bell would have been absolutely justified, and would have received the entire support of this Committee in withholding publication on this matter in view of the manifold difficulties of manufacture and the dangers of usage, as so ably explained by Prof. Carter Wood in THE LANCET (Feb. 20th, 1926, p. 414), in point of fact this course has not been adopted. So long ago as February, 1924, Prof. Blair Bell described and discussed the method of preparation of colloidal lead. Since that time many variations have been employed, but the general method has remained the same. The dosage and all the dangers and difficulties have likewise been published. Finality, however, has not even yet been reached. The very fact that the general body of practitioners appears to be ready to use the material if it be distributed without control, to the possible disparagement of the method and serious risk to the public, has impelled the Committee recently to protect the method of manufacture, as was done in the case of insulin.

2. With the dissemination of such erroneous ideas, it became inevitable that many would charge Prof. Blair Bell with "making hay while the sun shines," and say that he is keeping the treatment in his own hands, is exacting exorbitant fees, and is rapidly amassing a fortune by the employment of what to all intents and purposes they assert is a secret remedy. This charge is wholly contrary to the truth.

The Liverpool Cancer Research Committee have evidence that during the first five years 75 per cent.

---

[2] Infections of the Hand. Lea and Febiger. Fifth edition. 1925.

of the 200 odd patients treated were virtually charity patients, some few paying a nominal fee for accommodation, the majority being treated free of all cost. In other words, during the first five years since the initiation of the treatment Prof. Blair Bell has received remuneration from at most 75 patients—that is, an average of 15 each year. Nor, considering the benefit conferred, can the remuneration be regarded as other than most moderate.

Feeling acutely the charges circulated against him—often by men he had regarded as friends—at the end of four years a cheque for the whole amount charged for treatment was sent by him to the Cancer Research Committee. This cheque the Committee refused to accept. At the end of last year, on his return from America, when, for the first time, there was a large influx of patients, Prof. Blair Bell approached the Cancer Committee again asking them to receive all the fees for treatment, at the same time becoming themselves responsible for all necessary expenses. Knowing how gravely his intense preoccupation with cancer had interfered with his gynæcological practice, the Committee would not consider this offer. They made the counter offer, which has been accepted, that for his services as Director he should, from Dec. 1st, 1925, receive a stipend like the rest of the staff. In return the Committee assume all responsibilities for the housing and maintenance of the cancer patients under Prof. Blair Bell and the clinical staff; they receive all the fees and place all the books detailing income and expenditure under the weekly supervision of a well-known accountant. They have taken under their control the nursing home previously occupied by Prof. Blair Bell's gynæcological cases and have, in addition, bought and furnished another. Out of the moneys received they are continuing the stipends of those of the staff engaged in research, and are enlarging that staff, and they have by resolution agreed that all moneys over and above those expended as aforesaid shall be devoted to the furtherance of medical research.

We may add that these arrangements have been submitted to the President of the General Medical Council and have received his personal approval. Further, to secure their position, the question of incorporation is being considered by the Committee.

It is felt by all engaged in this work that, if it can be generally known that Prof. Blair Bell and the clinical staff are not benefiting to any unusual degree by this work, but are by their labours supporting the entire burden of the laboratories and clinical organisations, there may be greater confidence in, and greater sympathy with, what promises to develop into a very wonderful advance in the treatment of a most terrible state.

We enclose a copy of the circular letter which has been drawn up and sent by the Director to all doctors who have written to ask for treatment for their patients.

Signed, on behalf of the Liverpool Cancer Research Committee,
J. A. SMITH,
*Chairman.*
REX D. COHEN,
*Treasurer.*
J. GEORGE ADAMI.

*Liverpool, Feb. 23rd, 1926.*

[ENCLOSURE.]

DEAR SIR,—Thank you for your letter. You will understand that we are engaged in a scientific investigation, and have regarded our clinical work as a test of the findings obtained in the laboratory. We do not pretend and never have pretended that we have a "cure for cancer." Nevertheless, the ultimate aim of all such work is that, and we are prepared to take suitable cases that can come for consultation in the first instance, provided they are fully informed:—

1. That consultations are arranged in order that it may be determined whether the case is suitable for further investigation. A consultation does not mean that, *ipso facto*, the patient will be taken for treatment.
2. That the treatment itself may be dangerous.
3. That the treatment is experimental in nature.
4. That there is no guarantee whatsoever as to the result.
5. That patients must, if they come, place themselves unreservedly in our hands, and continue the treatment so long as we think it advisable.
6. That accessory treatment, such as X rays and operation, may be necessary.
7. That, if an operation has been performed, a section must be sent in advance.
8. That *all* fees are handed over to the Cancer Research Committee.

Yours very truly,
W. BLAIR BELL,
Director.

---

# MEDICINE AND THE LAW.

### *MORE ACTIONS AGAINST DOCTORS.*

IN addition to the action for negligence brought by Mrs. Venn against Dr. Todesco and Dr. Elder (discussed in a leading article on p. 560) two other actions against doctors were heard recently in the law-courts. In one of them Mrs. Norris claimed damages against Dr. W. A. MacWilliam, of Norbury, for alleged breach of contract and for personal injury, said to be due to his negligence in treating her at childbirth. She also claimed £430 special damage. The defendant denied the negligence and counterclaimed for his unpaid fees. The case presented no new point of general principle. After a careful hearing before the Lord Chief Justice it fortunately reached a final decision, Dr MacWilliam succeeding at all points.

The second case was one of greater difficulty and less finality. The facts, as stated in the *Times* report, were these. An ex-officer, Captain F. Hume-Spry, late R.F.A., was invalided out of the Army in 1917. Suffering from neurasthenia he was examined on behalf of the Ministry of Pensions in 1920, and entered one of the Ministry's hospitals. He passed through other hospitals and in 1923 went to Latchmere. Two months later a medical certificate was signed for a reception order under the Lunacy Act, and he was removed to the Old Manor Asylum, where he remained under a second certificate. Later he left the asylum, a doctor having certified that there was sufficient cause to release him. He then began two actions, one against the doctors who had certified him for removal and retention, the other against his wife and other persons for conspiracy. Prima facie these proceedings against the doctors were blocked by Section 330 of the Lunacy Act of 1890, if they had acted in good faith and with reasonable care. Under the usual legal machinery in chambers the action was stayed. The plaintiff appealed to Mr. Justice Bateson, who confirmed the order staying the proceedings, but granted leave to appeal further. The Court of Appeal reversed the order and directed that the action should proceed. Under the statute the sole question for the judges at this stage was whether or not they were "satisfied that there is no reasonable ground for alleging want of good faith or reasonable care." It was perfectly clear that the judges could not be thus satisfied, for the plaintiff was able to produce affidavits sworn by medical practitioners testifying to the contrary. "It might be said," observed Lord Justice Bankes, "that it was rather surprising to find a body of medical men who could come forward and say of others that they had not only acted without reasonable care, but also with want of good faith; but in this case there were two medical men who had come and pledged their oath upon both points." The court could not disregard such testimony; the case must go to a jury. The learned judge was careful to say that he expressed no view on the merits of the case, nor whether the affidavits contained opinions which a jury was likely to accept.

### *PROFESSIONAL SECRECY AND THE DANGEROUS DRUGS ACT.*

The recent prosecution of Dr. George C. Kingsbury, for supplying morphine contrary to the Dangerous Drugs Act, raised important professional issues. Counsel for the prosecution made it clear that not the slightest reflection was made upon the defendant's personal honour; the case was one, however, of much more than personal interest. The facts seem to have been undisputed. Dr. Kingsbury, having moved from the North of England to London, and having become a barrister-at-law, no longer carried on a general medical practice, but occasionally saw some of his old patients in a friendly way. Amongst these were two morphine addicts. One of them, a woman, he succeeded in curing. The other, a man of 70, he was treating, by the method of gradual withdrawal, with good prospect of success. Dr. Kingsbury purchased a supply of morphine from a chemist for a period of a year or more and personally handed the tablets to the patient whom he was treating gratuitously. The prosecution said that the doctor must keep a register in the prescribed form or else a day-book containing the patient's name and address. Dr. Kingsbury refused to disclose this information. He contended that a consulting physician in personal charge of a case is not obliged to keep any record; he added that thousands of doctors were never asked to keep these registers and never would. The magistrate treated the prosecution as a test case, convicted the defendant, and imposed what was euphemistically called the nominal penalty of 25 guineas. Dr. Kingsbury intimated that he would ask for a case to be stated with a view to appeal.

The Home Office, it appears, is seeking to ascertain how far it can go under its present powers. After studying the report of the recent Departmental Committee on Morphine and Heroin Addiction, one certainly retains an impression that the circumstances of Dr. Kingsbury's case were therein recognised as not wholly covered by existing legislation. If this be so, it seems undesirable that so big an issue should be dealt with by pressing prosecutions under the present law rather than by asking Parliament to pronounce afresh.

On the all-important question of the confidential relations between doctor and client the recent report had something to say. It recognised the disadvantages of impairing those relations. It observed that public opinion and the legislature have in some instances regarded the interests of the community and of the patients themselves as outweighing the interests of professional secrecy; but the report added that "each proposal for extension of this principle to a new group of cases must be considered on its merits." With this recommendation the medical profession would probably be prepared to agree, provided that the proposals are to be considered by public opinion and Parliament rather than by the police-court.

## VIENNA.

(From our own Correspondent.)

### *The Problem of the Expatriated Practitioner.*

Ever since the end of the war there has been serious trouble over the nationality of people born in the non-Austrian States of the old Empire, who have taken up their abode in what is now called the Austrian Republic. The right to practise medicine here is limited to Austrian subjects, but the various peace treaties have assigned many practitioners to other countries—countries whose language they may not even know. Being unfamiliar with its customs and people they have no desire to get to their native land, although—mainly for military reasons—their countries claim them. Out of about 5900 practitioners fully 27 per cent. are not Austrian born, whilst in Vienna itself the proportion of doctors technically not Austrians reaches about 39 per cent. It would be utter ruin for them to be uprooted and to leave Austria, or to lose the right to practise here. The Ministry of Home Affairs has accordingly decided to nationalise unconditionally all persons born in the former Austrian Empire who were in practice here before 1920. Other "aliens" must apply for nationalisation, and their applications will be considered in a most liberal sense. The Government has also begun negotiations, now nearly complete, for obtaining full reciprocity in this respect with all the seceding States, especially as regards the frontier cities and health resorts.

### *Fees between Medical Men.*

The Vienna Medical Council has repeatedly considered the relations between medical men who render one another medical assistance. It was understood, of course, in older, better times that such services were gratuitous, but now, with changed conditions, the views of the majority of doctors have changed also. It must be said that under the old system the doctor and his family were for the most part worse off than private individuals, who in case of illness could summon the family physician as often as they thought fit. The medical man, on the contrary, could not bother his doctor too much because the service was gratuitous, and many a necessary call was never made because of these scruples. More than two years ago suggestions were made in the German (Austrian) medical papers by a number of practitioners who wanted a ruling on these questions, and at a recent meeting of the Medical Council a resolution was presented and adopted, to the effect that every service requires adequate payment and that medical men and their families should be treated on the same principles as other private patients. It was suggested that, for the time being, the profession should accept the following proposals: (1) Every medical man who is offered a fee for the treatment of a medical man or the family (wife, children) dependent on him for their upkeep is bound to accept it and to hand it over in a tactful way to the funds of a medical or other charitable institution or to the Medical Organisation. (2) Such fees shall be offered at a scale not exceeding that arranged between the Organisation and the sickness club of the Civil Service men. These provisions, it is hoped, will remove the qualms of patient and practitioner. They will also suit the patient's pocket, for the fees are only about one-third of those paid by private patients, and though the doctor is bound to accept an offered fee, he does not ask one. These arrangements are, as stated above, only temporary. There is some question whether it would not ultimately be more convenient to have a central clearing office, so to say, for the payments, so as to do away with the awkwardness—to some doctors, at least—of offering fees to a colleague. It is intended that funds from this source shall be used to ensure better nursing for medical men requiring treatment in hospitals or nursing homes. Definite regulations will be suggested after the present scheme has been tried for one or two years.

### *The Title of "Specialist."*

In conformity with the views held by the large majority of medical men, it has been decided by the Organisation that a doctor may not style himself specialist and become a member of the officially recognised Association of Specialists until he has fulfilled certain requirements. These are: Qualification as M.D.; three years' study in a hospital or clinic devoted only to the specialty selected (which must include at least one year's service as house surgeon or house physician); and another year as resident or junior surgeon or physician in a general hospital. This means that a specialist has seen four years' hospital work before he becomes a fully-fledged member of the Association and gains the right to settle down in practice. Difficulties have now arisen over doctors who are in practice already or are in the act of taking it up, but have not had that kind of elaborate preparation. In order to regularise their position it has been decided that doctors who graduated before Jan. 1st, 1923, and have had at least two years' specialist training may apply for membership of the Association of Specialists. Those who have been in specialist practice for two years or more are exempt from all restriction.

### *Fewer School-children and Fewer Males.*

The census of school-children in December, 1925, has shown that the total number of pupils in all schools from 6 to 18 years of age is 61,060 less than last year. Statistics of the Board of Health of Vienna show that to-day we have 200,288 children in the age-period up to 10 years, whereas in 1914 the corresponding number was 330,885. In other words, that age-group which represents the coming generation shows a drop of 30 per cent., and this fall will be the more marked when the present generation gradually dies out. Furthermore, in 1914 the relative number of males to females was 1000 : 1077. At present it is 1000 : 1251—i.e., there is a surplus of females of over 25 per cent., and this is likely to increase still further since amongst children up to 15 years the disparity is even greater. It means that in ten years no less than 30 per cent. of the Viennese women will be doomed to celibacy, and as the population of the city is even less than in 1910 (the loss is 165,041, or over 10 per cent.), the birth-rate is not likely to reach a high level.

## CANADA.

(FROM AN OCCASIONAL CORRESPONDENT.)

### *Proposed Hospital Tax for Montreal.*

THE hospitals of Montreal are in financial difficulties, and it is obvious that their cost will increase rather than diminish as time goes on. At present they are maintained chiefly by the donations of a comparatively small group of citizens, and there is an increasing feeling that this is a bad arrangement. Paying patients in the public wards do not contribute to the cost of their maintenance, and thousands of in-patients are housed, fed, and treated gratuitously The grants given by provincial and municipal governments are very small. Recently it has been proposed that a tax should be levied to meet the annual deficits of the hospitals. This proposal has been generally endorsed by the citizens, and the only question now to be answered is: What is to be taxed? Luxury taxes on motor-cars and liquor sales have been suggested, but it is objected that motor-cars are not luxuries—though few have the hardihood to say the same of liquor. A tax on motor-cars might be equitably distributed, it is thought, over the holders of motor-car licences, upon a graded scale varying from 1*d.* a week on cars costing £200 or less, up to 3*d.* a week upon more expensive cars. Liquor is under State control in the Province of Quebec, and a substantial portion of the revenue from a liquor tax would be collected from the travelling public who freely patronise the Government stores. A small tax on these people would be no hardship. The form which the taxation shall take is a matter for discussion, but it is encouraging to see how cordially the proposal has been received by the community at large. Perhaps a way out of the difficulties of the hospital situation may really have been found.

### *The Birth-rate in English-Speaking Canada.*

The birth-rate in English-speaking Canada continues to decline. In June last, the most recent month for which the record in the Bureau of Statistics is complete, 12,396 babies were born in eight provinces, whereas in June, 1924, 13,344 infants were born in the same area, and in June, 1921, 13,060. (These statistics do not include stillbirths, of which there were 427 last June.) During the past four years, it is stated, the birth-rate for all Canada, exclusive of Quebec, has dropped from 26·5 per 1000 of population to 22·1. Maternal mortality, however, is also diminishing. In June, 1925, it amounted to 5·5 per 1000 living births, compared with 6·4 in the same month in the previous year. The infantile mortality was 67·8 per 1000 living births, which also represented an improvement.

### *University News.*

In almost all departments of McGill University the standards for entrance have been raised. In the faculty of dentistry the change is especially notable, and a two years' course in arts as a preliminary to the four years' dental course is now required. No changes of importance have been made in the curriculum of the medical student who has two years' general education in arts followed by five years' medical study.

Dr A. A. James, of the Western University, London, Ontario, has been given a grant of £200 by the Advisory Council for Scientific and Industrial Research to assist him to continue the work on the effect of liver extract on blood pressure, on which he has been engaged for some time with Dr. Laughton.

A Department of Child Study has been started at McGill University and has been endowed with £2000 a year for five years. A nursery school of 20 pupils has recently been opened.

On Feb. 13th a portrait of Dr. Francis J. Shepherd, Emeritus dean and professor of medicine at McGill, was unveiled in the University. Dr. Shepherd, who is now 76 years of age, gave an interesting account of the changes he had seen in 56 years at the school.

Much regret is felt at the death in Montreal of Dr. Thomas Workman Burgess, who was born in 1849 and served as surgeon to the North America Boundary Commission. Later he became professor of mental diseases at McGill University, and was well known as a trenchant and able writer on psychiatry.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *Street Accidents in Dublin.*

THE police authorities in Dublin have lately been giving attention to the prevention of street accidents, and have issued an appeal to all users of the streets to help in reducing the number of accidents. Large posters have been printed and distributed to all important owners of street vehicles, to be displayed in garages and other places where they can be seen by drivers. The posters set out in simple language what is to be done to avoid accidents, and those in charge of vehicles are asked to coöperate with the police on the lines suggested. It is pointed out that the street accident rate in Dublin has doubled in two years. In 1925 there were 1103 traffic accidents, in which 29 persons were killed, 88 seriously injured, and 595 received minor injuries. Handbills have been issued advising pedestrians and cyclists how to behave in the streets. In some cases the punishment of persons culpably responsible seems unduly light. Last week a motorist was convicted of the manslaughter of a young boy in a Dublin thoroughfare. Having killed the boy he drove off, nearly killing a policeman who tried to stop him. The judge in sentencing him said that he had killed the boy "by wilful, reckless, negligent driving." Yet the sentence imposed was only six months' imprisonment with hard labour.

### *Sanitary Condition of Monaghan.*

Dr. Robert McDonnell, one of the medical inspectors of the Department of Local Government and Public Health, recently investigated the sanitary condition of the town of Monaghan, and the state of affairs he describes in his report is shocking. "Wretched hovels," he says, "inhabited by human beings, without light, without space, and without the ordinary conveniences of a dwelling-house, go to make up the lanes and side streets of the town. The byres, where the milk consumed in the town is produced, are on a par with the slum houses—dark, damp, and dirty. Healthy, clean milk could not be produced in some of the cowsheds visited by me." There was, he said, no inspection of milk or meat supplies. The surroundings of the slaughter-houses were insanitary. The sewage arrangements were very bad. There were only old stone drains, and many streets had no sewers at all. The old ones were worse than useless, and were a grave menace to the public health of the town because they could not deal with the volume of sewage requiring removal, and their discharge caused gross pollution of an open river which runs close to the town. About 200 dwelling-houses were without sanitary conveniences of any kind. The lanes and alleys were in an appalling condition.

The conditions disclosed by Dr. McDonnell are almost incredible unless it is remembered that there is as yet no public health administration in the ordinary sense in Ireland. Only two cities—Dublin and Belfast—have whole-time medical officers of health, and it was only last year that the legislature of the Free State made it compulsory for county health authorities to appoint whole-time medical officers of health. It has not been possible yet to put this provision into force, but preparations are being made to do so.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. A. K. Smith-Shand is placed on the Retd. List with the rank of Surg. Capt.

### ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub.-Lt. R. R. Dodd to be Surg. Sub.-Lt.

## ROYAL ARMY MEDICAL CORPS.

### TERRITORIAL ARMY.

Capt. G. F. Wilson is granted pay and allowances of his rank.

Lt. I. Morgan ceases to hold a commission in the Territorial Army.

G. Fitzmaurice Keatinge (late R.N.V.R.) to be Lt.

### MILITIA.

Capt. G. A. Cole to be Maj.

## ROYAL AIR FORCE.

Flying Officer R. H. Stanbridge is promoted to the rank of Flight Lt.

Flight Lt. H. E. Flavelle (Capt., Army Dental Corps) relinquishes his temporary commission on return to Army duty.

## INDIAN MEDICAL SERVICE.

Maj. Narendra Singh Sodhi to be Lt.-Col.

The King has approved the restoration to the active list, from the temp. non-effective list, of Capt. Pirojsha Merwanji Antia.

The King has approved the retirement of Lt.-Col. W. McM. Pearson.

## FOREIGN DECORATIONS FOR SERVICES DURING THE LATE WAR.

The King has given unrestricted permission to the following officers to wear the Médaille de la Reconnaissance Française en Vermeil, conferred upon them by the President of the French Republic: Brevet Lt.-Col. W. H. G. H. Best, R.A.M.C. (Special Reserve).—en Argent: Maj. H. D'Arnim Blumberg, O.B.E., T.D., R.A.M.C. (T.); Capt. A. J. Clark, M.C., R.A.M.C. (Special Reserve); Lt.-Col. H. Collinson, C.B., C.M.G., D.S.O., T.D., R.A.M.C. (T.); Maj. J. M. M. Crawford, O.B.E., R.A.M.C.; Capt. J. Jackson, R.A.M.C. (T.); Capt. L. de G. Joubert, C.A.M.C.; Capt. J. A. Lorrain, C.A.M.C.; Maj. J. A. Lussier, C.A.M.C.; Maj. M. J. Mahony, D.S.O., T.D., R.A.M.C. (T.); Maj. A. J. Mollison, Aust.A.M.C.; Maj. G. S. Parkinson, D.S.O., R.A.M.C.; Temp. Capt. W. H. Rayner, R.A.M.C.; Lt.-Col. P. Z. Rheaume, C.A.M.C.; Maj. A. N. Rivet, C.A.M.C.; Lt.-Col. E. Ryan, C.M.G., D.S.O., R.A.M.C.; Maj. Edouard Charles Saint-Pierre, C.A.M.C.; Col. A. D. Sharp, C.B., C.M.G., T.D. (T.); Maj. G. H. Stevenson, O.B.E., M.C., R.A.M.C. (Special Reserve); Capt. E. S. Stork, D.S.O., R.A.M.C. (T.); Capt. E. W. Strange, R.A.M.C. (T.); Col. C. P. Templeton, C.B.E., D.S.O., C.A.M.C.; Col. A. G. Thompson, C.M.G., D.S.O., retd. pay; Maj. A. C. Turner, D.S.O., T.D., R.A.M.C. (T.); Temp. Capt. D. Ll. Williams, M.C., R.A.M.C.; Maj. H. K. Griffith, T.D., R.A.M.C. (T.); Temp. Capt. J. Jardine, O.B.E., R.A.M.C.; Maj. W. F. McAllister-Hewlings, R.A.M.C. (T.); Capt. Ernest Brooke Pike, R.A.M.C. (T.); Capt. W. G. Shakespeare, R.A.M.C.; Maj. H. C. Sidgwick, O.B.E., R.A.M.C.; Capt. E. M. Townsend, M.C., R.A.M.C.; Maj. G. W. W. Ware, D.S.O., R.A.M.C.

Dr. Thomas Lawson Craig (senior medical officer) has been appointed a Member of the Executive Council of the Gambia and an Official Member of the Legislative Council of that colony.

"Audi alteram partem."

## TREATMENT IN DISEASE OF THE NERVOUS SYSTEM.

*To the Editor of* THE LANCET.

SIR,—The excellent Lettsomian lecture in your issue of Feb. 20th by Dr. Farquhar Buzzard is so transparently honest that it may seem rather ungracious to offer any criticism; however, as it appears to me to require some elucidation I reluctantly undertake the task.

Dr. Buzzard is evidently anxious to tell the truth, the whole truth, and nothing but the truth, but, not infrequently, he so glosses over the truth that it would be impossible for any patient to fully realise the hopeless character of the opinion which he has heard expressed. Although I have dabbled a little in nervous diseases, the utter futility of treatment, as carried out in the present day, has prevented me from ever specialising in the subject, and I only now present my opinion for what it may be worth. I have often said that any real advance in the treatment of disease must be on the lines of prevention. Here there is practically an untilled field, but the great drawback to its cultivation is that prevention does not pay. In 1907 and often since I have suggested that payment should be by results, and in the case of death the medical attendants might be required to pay the funeral expenses. If this were in vogue in the treatment of nervous diseases neurologists might often end their days in an asylum for the destitute. Occasionally patients, and often their friends, "want to know the worst," so that the consultant is frequently tested as to how to tell the truth, the whole truth, and nothing but the truth without any unnecessary circumlocution and without any exposure of his own ignorance.

The helplessness of the neurologist in dealing with lesions of the upper motor neurone points to the advantage of prevention over any attempted cure, and this is by no means a hopeless task if more attention were paid to the vascular system. There is no insuperable difficulty in preserving the blood-vessels of the brain, as well as elsewhere, in a healthy condition, even to advanced age.

Dr. Buzzard expresses his opinion of the uselessness of electricity in these upper neurone cases in no uncertain language, and I do not cavil with him on the point, though I think his opinion might be more accurately expressed. "If all the current wasted in a year on the limbs of hemiplegic patients could be stored in accumulators, the Prime Minister's scheme for supplying electricity to the country would be rendered superfluous." He surely should have based his conclusion on reliable evidence as to the amount of current thus running to waste. It might then have been possible to calculate how many miles it would drive a tramcar or an electric train. Our electrical engineer informs me that the electricity supplied by the Liverpool Corporation in the year 1925 amounted to 167,409,433 units, and you might add another sixth for private manufacture in large works. I have no hesitation in hazarding the assumption that all the electricity used for medical purposes throughout England in ten years would not supply Liverpool for one hour, unless, perhaps, in the middle of the night, when deadly silence prevails, and only the street lamps are dimly shining. The Prime Minister had, therefore, better go on with his scheme until he gets more reliable evidence as to its superfluity.

In dealing with the lower motor neurone electricity seems almost permissible. In progressive muscular atrophy, bulbar paralysis, and amyotrophic lateral sclerosis you may say to the patient: "Some of your muscles are wasting and becoming weak; you must have some massage and electrical treatment to strengthen them, and I will give you some injections of strychnine in order to tone up your nervous system." Here, again, I think the condition of the vascular system is worthy of some consideration.

In an address which I gave in London in 1924 the following paragraphs occur:—

> "*Progressive Muscular Atrophy.*—The acute form of anterior poliomyelitis occurs chiefly in children, and is an infectious disease which usually affects the lower extremities; this special selection is probably due to a greater vascular supply to the lumbar enlargement of the cord.
>
> "The grey matter of the cord is supplied by the anterior spinal artery, and in early age the artery is very pliant and ready to supply the blood according to the demands of the part. In these cases the best treatment is absolute rest; elevate the hips and apply a spinal ice-bag over the lumbar and lower dorsal region of the cord. A febrifuge with *salicylate of sodium* is useful.
>
> "In later years progressive muscular atrophy is a degenerative lesion and affects chiefly the upper extremities, and is due to an insufficient supply of blood to the cervical enlargement. So far as my experience goes it occurs mostly in teetotallers and milk drinkers. The excessive supply of calcium leads to contraction and sluggish circulation in this small artery and its branches, with degeneration and calcification.
>
> "When the disease occurs it is too late to influence the *rigid vessel through the depressor nerve. The treatment,* therefore, should be preventive both in its origin and progressive character
>
> "I prefer claret and lemon squash to milk and hard water. Exercise rather than a life of ennui."

Dr. Buzzard concludes his sombre lecture as *follows*:—

> 'In this my first of three lectures I have chosen for discussion some disorders of nervous function the causes of *which we are powerless to influence or control.*"

I am now more than ever convinced that, owing to the hopeless and helpless muddle of therapeutics, the only salvation for the race consists in healthy breeding. *Mens sana in corpore sano*, and preventive medicine.

I am, Sir, yours faithfully,

Liverpool, Feb. 25th, 1926. JAMES BARR.

## FAMINES IN THE TROPICS.

*To the Editor of* THE LANCET.

SIR,—Famine at the present time in the Gabun, French Equatorial Africa, with, according to Dr. Albert Schweitzer, its attendant dysentery and "human beings who are mere skeletons and with terrible sores on their feet," invites attention to an onerous *phase of work* which falls at intervals to the medical man in the tropics. Records of past famines and the means employed for relief of distressed populations *accordingly are of* value to them, *in arriving* at decisions as to principles to be advised. In this spirit will doubtless be consulted the recently published "*History of India*" by Prof. *Dodwell, in which modern* famine relief measures as applied in India receive attention. But, "history as she is wrote" and facts of the past notoriously *are liable to differ, and, in this* case, I think it desirable, in common justice to the members of the Services employed under the Government of Madras and their many *philanthropic helpers* in the great famine of 1876–78, to point out that the scathing assertions made by the author at p. 79 of his work are not justified by the official documents[1] upon which he states he has relied for information.

After suggesting that "great variation in laxity nd strictness" in administration existed, he assigns Bombay the credit of prompt action in opening great relief works" and using special scrutiny as gratuitous relief. "*But,*" he states, "in Mysore d Madras attempts were made to encounter an lmost overwhelming disaster on the principles at had been applied to the scarcity in Behar, until e Viceroy Lytton had visited the scene in person nd secured the adoption of methods employed in ombay, which he perceived *were less wasteful not nly of the resources of the State, but also of human fe*" (italics not in the original). This would imply hat the Government of Madras were untrammelled by the Government of India from October, 1876, to August 20th, 1877, when the Viceroy made the personal visit specified; whereas, at the very origin of the famine, the Government of India not only claimed but insisted upon its absolute right of dictating the policy of the subordinate Governments of Madras and Bombay. As to Mysore, if matters there were inefficient, the Government of India was directly responsible, while so far as Madras is concerned, the author's statement of incidents is incorrect.

At the critical period as to the failure or not of the monsoon, in the *presence of stocks of grain* "held back" by the well-organised and astute Chetty caste of merchants peculiar to the Madras Presidency, with instantly resulting artificial famine prices, the Government of Madras desired to contract for the importation of 30,000 tons of rice to be held as a reserve. After seven days' delay in replying to telegrams on the subject, the Government of India, which in the Behar famine had countenanced the importation of 480,000 tons of grain, gave a flat refusal. This is the sole justification for the historian's allusion to the Behar "principles." The Government of Bombay were saved from facing the same "profiteer" *difficulty by splendid private* philanthropy. The Government of Madras had given to the Government of India timely warning of possibly impending famine, and definitely suggested concentration of labour on great works as "most necessary," but sanction was refused; (*a*) local petty works near villages solely were approved. This implied the *organisation of petty works to serve a population of* 20,000,000 scattered through 80,000 square miles.

These two refusals were followed by the Govern*ment of India deputing a delegate to the Madras* Presidency, armed with instructions which forcibly suggested economy. In the presence of famine prices and absence *of labour possibilities*, within six weeks of the delegate undertaking duty, as a result of his special method of elimination, (*b*) a reduction of 500,034 persons employed on relief works, or receiving gratuitous relief, was carried out. Against the protests of the then Sanitary Commissioner for the Government of Madras, Surgeon-Major (subsequently Surgeon-General) Cornish, C.I.E.—not only an expert sanitarian, but one who had for many years investigated specially and reported on Indian dietary—the wage on relief works was (*c*) reduced to the equivalent of one pound of grain with one half anna (say, three farthings) to cover the cost of condiments, essential pulses, fats, and antiscorbutics. Therefore, on a diet yielding 1010 calories[2] represented in rice (practically the only grain then available) per adult man, not only tasked labour but frequently, in addition, many miles of *march daily* to and from the relief works were demanded. From Jan. 31st, 1876, to May 22nd, 1877, this diet was in force, when, in view of strong public opinion, with the approval of the Secretary of State and the concurrence of the Government of India, it was withdrawn.

In para. 7 of his Minute of August 12th, 1877, the Viceroy conceded that the policy of his Government in forbidding large works at the origin of the famine was erroneous. In the meantime, the effort to close petty works opened as originally ordered accentuated the aimless wanderings and begging which resulted from policy (*b*), whilst the effect of policy (*c*) was to crowd the hospitals and relief camps with masses of men, women, and children rendered *absolutely* unfit for the work by *reason of malnutrition* A "trial census" within the famine area of the Madras Presidency showed that the united results of factors (*a*), (*b*), and (*c*) had been to bring about a decrease of 3,000,000 in the population under the heads of emigration, decline of birth-*rates*, and increase of deaths. It is possible to *show* that following consultation with the Government of Madras, strengthening of staffs and improvements in *details* of organisation were adumbrated *after* the visit of the Viceroy, but the fact remains that no human efforts could get rid of the effects of the false policy on which the campaign had been opened. Cornish, the sanitarian, had correctly protested that "in consideration of the fact that diseased conditions dependent on insufficient food follow many months after the cause has passed away, I apprehend that a heavy and unusual mortality will continue." The "practical" lay administrators who evolved the theory of merely sustaining life as distinct from fitness for labour, which should have been the goal, were confronted with the curious psychology and the *literally* irremediable state in subjects of prolonged chronic starvation, as contrasted with results in the acute form, which alone could have afforded any basis for their disastrous theories.

---

[1] These are sufficiently found in the Famine Campaigns of uth India, by *Digby (two volumes)*, Longmans, 1878.

[2] Calculation for unpolished rice according to Plimmer.

If both the Presidencies of Madras and Bombay were subject to the overrule of the Government of India, and if, as was the case, in both, the European and Indian officials concerned worked in the interests of the saving of life to the limit of human endurance, and yet a difference in results is demonstrable, this was solely due to the latter Presidency in the early period of famine adopting Nelson's method when obeying the orders of the Government of India.

I am, Sir, yours faithfully,

W. G. KING,
Colonel, I.M.S. (ret.)

Hendon, N.W.

## STRICTURES OF THE URETHRA.

*To the Editor of* THE LANCET.

SIR,—I have read with great interest the article on Strictures in THE LANCET of March 6th by Mr. Girling Ball. In the main his description is admirable, but it does not advance the question of treatment far beyond that which was in vogue 15 or even 20 years ago. He only carries dilatations to 14/16 English—i.e., 24/27 Fr. Now it can be easily proved, by anyone who likes to take the trouble to make the observation, either on the cadaver or on the living subject under *efficient* local anæsthesia, that with the exception of the fossa navicularis and the external meatus the adult human urethra can be dilated easily to 45 Fr. (28 English). This observation was made in Germany years ago towards the end of the last century. It is so definite that I regard it as axiomatic that, if a urethra does not dilate to this calibre easily, it is the seat of an abnormality requiring closer investigation. In nine cases out of ten this abnormality will be found to be a stricture of large calibre which is quite capable of being treated and cured.

It is often impossible to detect such an early stricture with sounds because an instrument large enough could not pass the external meatus. The Kollmann, or similar expanding dilator, must be used. Again, if we are dilating a smaller stricture, why stop at 27 Fr. when it is possible to go on to 45, so much nearer the healthy natural size? Nature does not provide so large a canal for nothing, but it is impossible here to go into what I believe to be the reasons for this; suffice it to say that they are important and have a bearing on the health of the patient in later life.

Again, Mr. Girling Ball states that pain during the passage of instruments "can *sometimes* be avoided by the instillation of 2–4 per cent. novocaine." Now if efficient dilatation is to be carried out to the limits I have mentioned pain must be avoided *always*. Novocaine, whilst it is an admirable local anæsthetic when injected beneath the epithelium, is not good when applied to a mucous surface, as it lacks penetrating power. A 2–4 per cent. solution of cocaine is the only local anæsthetic possessing this power to a satisfactory degree, but its dangers negative its use except under special conditions. Fortunately, if the cocaine is combined with sodium bicarbonate, it is possible to obtain a solution which is of such low concentration that, in an experience of its use extending over many thousands of cases, I have never seen a single unpleasant symptom. The solution is a 0·5 per cent. solution of cocaine hydrochloride with a similar concentration of sodium bicarbonate, and it is a matter of standard routine to use it on every case in which I propose to pass instruments through the urethra. It gives all the anæsthesia that is required. Recently borocaine has been tried and the results are so far encouraging.

I am, Sir, yours faithfully,

H. L. ATTWATER, M.Ch., F.R.C.S.,
Assistant Surgeon to All Saints' Hospital

Wimpole-street, W., March 7th, 1926.

## HAGIOLOGICAL THERAPEUTICS.

*To the Editor of* THE LANCET.

SIR,—Your readers may be interested to hear of a method for testing a new remedy which was employed in the ninth century, and is recorded in the "Chronicon Turonense Magnum," a monkish chronicle probably of the twelfth century.

In 852 the Danes, under Rollo, threatened Tours, but as the floods prevented their attacking it they turned to Marmoutier (Majus Monasterium), about a mile up the Loire on the north bank, killed 116 monks, tortured the abbot to make him reveal the treasures, but in vain, and retired. As they threatened to return, the canons of Beatus Martin of Tours conveyed the body of the saint to Auxerre for safety. The result was a large increase in the miracles there, a large influx of pilgrims, and a large addition to the revenues of the Church of S. Germain, in which Martin's body was laid. The miracles were claimed by the canons of B. Martin to be his work, but the Auxerre clergy manfully (viriliter) asserted that they were the work of S. Germain. They agreed to test the question by laying a leper between the two saints and observing which side of him was cured. "Quid plura?" It was done, and the side next Martin was alone cured. But they very rightly thought that this experiment should be controlled. The leper was therefore reversed, and his diseased half, now next to Martin, was at once cured. "And so the strife between the clergy was set at rest and the offerings were from that time paid to the servants of B. Martin."

It is not surprising to learn that 31 years later, when times were quieter and the Tourangeois asked for Martin back again, the Bishop of Auxerre refused, and the saint was only recovered by an armed force led by Ingelger Count of Angers, the ancestor of the Angevin line. The progress of the body was marked by the healing of all the sick along the route, including those who were not brought in contact with it, those who did not implore the saint's help, and even those who did not want to be cured (inviti), which was recognised as a proof of the saint's unusual clemency. It may be added that though it was December the trees broke into leaf and flower.

I am, Sir, yours faithfully,

London, March 8th, 1926. W. P. HERRINGHAM.

## THE RISKS OF THE SAILOR.

*To the Editor of* THE LANCET.

SIR,—Many will be glad to note the prominence which is given regularly in THE LANCET to the exposure of seamen to gross defaults of social hygiene. When a ship comes into port its crew is regarded as the legitimate prey of prostitutes, the vendors of poisonous and doctored liquor, and the keepers of unlicensed lodging-houses. It is in evidence that in numerous cases prostitutes under treatment for venereal disease in its infectious stages in hospitals and infirmaries take their discharge from these institutions on the arrival of an expected ship in port, in order that they may be in readiness to meet the sailors as soon as they are paid off. In these circumstances it cannot be wondered that the number of cases of gonorrhœa and syphilis among seafaring men is rather high, and that sailors, having contracted the disease at one port, frequently spread the infection at the next calling station of their ship. If it were possible to provide healthy recreation in the open air with organised games such as football, hockey, &c., for these young men, experience teaches us that the infection rate would materially diminish. When the Contagious Diseases Acts were repealed in 1885 the number of cases of venereal disease in the Aldershot Command was about 327 per 1000. In 1911 it had diminished to a little more than 33 per 1000. This was mainly due to the efforts made by the officers, both combatant and medical, to provide out-door games, sports, and other recreations to give the soldiers some healthy occupation when off duty. Conferences are now being held in the seaport towns, and committees appointed, to promote the same state of affairs for seamen when on shore. Great and most valuable work is being done by the various organisations and associations which look after the welfare of sailors, but the coöperation of local authorities, athletic, and sporting clubs who have suitable grounds is required to make a success of the movement. If it were possible to meet and get hold of the boys and younger members of the crew on the arrival of a ship and offer them healthy and health-giving amusement, the number of risks of infection taken would be enormously reduced, with a corresponding decrease in the number of cases of disease. From a health point of view it is to be hoped that the members of our profession practising in seaport towns will, whenever possible, give their hearty support to this attempt to improve the health of our seafaring population. Measures are being taken in foreign seaports to provide the same facilities.

I am, Sir, yours faithfully,

London, March 8th, 1926. E. B. TURNER.

## THE INCIDENCE OF PHLEBITIS.

*To the Editor of* THE LANCET.

SIR,—I should be interested to know whether there has been a general increase in the number of cases of phlebitis of the veins of the lower limb during the past 12 months. In this district the number has been comparatively large and the history of each case similar—i.e., sudden onset with fever, a tendency to spread to the veins of the opposite limb, and a large proportion of pulmonary infarcts. In one case there occurred multiple cerebral emboli leading to extensive softening and progressive dementia. Since ordinary treatment appears to be quite ineffective in staying the course of the disease, a hint as to a specific bacterial origin would be valuable.

I am, Sir, yours faithfully,

JOHN WHITTINGDALE.

Sherborne, Dorset, March 8th, 1926.

## "IS CIVILISATION A FAILURE?"

*To the Editor of* THE LANCET.

SIR,—Your note on Sir Arbuthnot Lane's discourse upon the old question "Is Civilisation a Failure?" (asked long ago more poetically by Bret Harte) is most interesting, especially in the light shed upon it by Prof. John Dewey and Mr. Matthias Alexander. According to Sir Arbuthnot Lane, the failure of civilisation lies in an alteration of the simple mechanical relationship Nature intended us to maintain towards our surroundings, and this has caused alterations in human anatomy which have produced all the ills from which we suffer to-day. That the numerous and heavy calls which civilisation has made upon the human organism have resulted in failure to respond with sufficient rapidity to altered environment is an undoubted fact, and no doubt the lecturer obtained this information from Alexander's "Constructive Conscious Control," with which I know him to be acquainted. One fails to see, however, what "alterations in human anatomy" this failure either could cause or has caused in the short period during which man has been civilised. That it has resulted in serious *wrong functioning*, both in body and mind, is what Alexander has insisted upon in the work mentioned, and it is nowhere better seen than in the attitude of most of our lecturers on health to-day. What Alexander has done is to find a specific remedy for this wrong functioning in his technique of re-education.

I am, Sir, yours faithfully,

MACLEOD YEARSLEY.

Wimpole-street, W., March 4th, 1926.

## A HUGE EMPYEMA.

*To the Editor of* THE LANCET.

SIR,—I was particularly interested in the letter of Mr J. Cæsar, in the last issue of THE LANCET, giving the notes of two cases of empyema. The evacuation of eight pints of pus by the aspirator at one sitting is not quite a record, as I have myself drawn off over nine pints in a similar case. The notes of this case are, I think, of interest, in that the patient's symptoms were not sufficiently severe for him to consider himself ill enough to "report sick," until he was in a really serious condition.

While acting as ship's surgeon I was summoned to the forecastle to see a fireman aged 41. Temp. 103·5° F.; pulse, 140. There was an area of dullness extending from the right lower costal margin to the fifth intercostal space. I diagnosed pleural effusion, and the next morning I introduced a needle, under novocaine anæsthetic, in the eighth intercostal space, and was amazed when I drew off nine and a half pints of foul-smelling pus. Within an hour his temperature had fallen to 101° and his pulse-rate had become 110 per min. Two days later, on reaching port, I sent him to hospital. Six months afterwards I met him, and he told me that he had made an uninterrupted recovery in hospital, where he remained only 15 days, and, since his discharge from the hospital, had made a trip to the River Plate and back.

I am, Sir, yours faithfully,

D. GORDON ROBINSON,

Late Surgeon, Ellerman's Wilson Line.

Hull, March 5th, 1926.

## A DIAGNOSTIC SKIN REACTION FOR TYPHOID.

*To the Editor of* THE LANCET.

SIR,—The value of the Dick test as a diagnostic agent in scarlet fever consists in its ability to exclude the possibility of scarlet fever in those who fail to react. If the reaction to a Dick test be positive the patient may still not have scarlet fever. The test is therefore of limited value in the case of scarlet fever. But we may suppose that in England, at least, the great majority of the population are susceptible to typhoid fever, and it is therefore probable that were a skin sensitivity test, on the principle described in your annotation of Feb. 6th, ever perfected it would be of very little diagnostic value.

I am, Sir, yours faithfully,

Ohio, Feb 19th, 1926. J. ROSSLYN EARP.

---

SUSSEX EYE HOSPITAL.—The year 1925 marked the ninety-third anniversary of the Sussex Eye Hospital in Queen's road, Brighton. The governors are continually faced with financial difficulties, and with the strictest economy in every department the year 1925 ended with a deficit of £301. Legacies fortunately liquidated this sum and left a little over. It was pointed out, however, at the annual meeting of the governors on Feb. 10th, that at least another £300 a year was required if current expenses were to be paid out of current income. There is an overdraft of £171 due to the bank, and at least £1000 is needed to place the institution in a proper state of repair. The work continues to grow. In 1910 there were 211 in-patients during the year and 2572 out-patients; in 1925 the figures were 350 and 1005 respectively. A statute having been altered so as to permit the election of more than one patron, the Duke of Richmond and Gordon and the Earl of Chichester have been elected.

# Obituary.

## WILLIAM CHARLES SULLIVAN, M.D.R.U.I.,

MEDICAL SUPERINTENDENT OF BROADMOOR.

THE death, which occurred on March 1st, of Dr. William Sullivan, the medical superintendent of Broadmoor Criminal Lunatic Asylum, removes from the Government service a highly valued officer, while we shall no longer have the opportunity of putting before our readers his strong but well-balanced views on many of the medical questions which came within his special cognisance.

William Sullivan, the youngest son of Dr. W. K. Sullivan, a President of Queen's College, Cork, was born in 1869 and educated in Cork and Dublin. He graduated in medicine at the Royal University of Ireland in 1891, being later Stewart scholar in mental diseases, and then spent a considerable time in Paris, where he obtained his accurate acquaintance with French work in psychiatry. He decided to enter the prison service and his first appointment was in H.M. Prisons Liverpool, but he afterwards held office at Parkhurst, Holloway, and Pentonville. He was then appointed medical superintendent of the State criminal lunatic asylum at Rampton, a post which he held until he succeeded to the superintendency of Broadmoor in 1920, upon the retirement of Sir Richard Brayn.

He came prominently before the public as a member of the Advisory Committee appointed in 1916 by the Central Control Board (Liquor Traffic) to consider the conditions affecting the physiological action of alcohol. The particular reference of this Committee was to report upon the effects of health and industrial efficiency induced by the consumption of beverages of various alcoholic strength. The Committee was strongly composed with Lord D'Abernon as chairman, the others members being the late Prof. Cushny, Dr. H. H. Dale, Dr. M. Greenwood, Dr. W. McDougall, Sir George Newman, Sir Frederick Mott, Sir Charles Sherrington, and Sullivan, and to Sullivan personally much of the credit of the work done is due, for it was largely through him that the necessity for fundamental change in the hours during which public-houses may remain open became recognised as a necessity. The long afternoon break in public-house hours has led to a decrease alike in drunkenness and alcoholic morbidity, and none of the critics of the reform—there were and are many—have ever been able to gainsay the advantages obtained. Sullivan's presence on the Committee was due partly to a general appreciation of his administrative work among two classes where alcohol produces disastrous ravages, but particularly to the accurate information and sound views which he had placed before the public some ten years previously in a treatise on the whole subject of alcoholism, regarded as a chapter in social pathology.

Sullivan was a man of high literary ability, and his lectures on criminology and forensic medicine, delivered at the Maudsley Hospital, his editorial writing in THE LANCET and his contributions to the *XIX. Century and After*, and various home and foreign organs, all displayed an easy erudition and a power of speaking clearly as well as emphatically. These qualities were marked in his valuable treatise "Crime and Insanity" written after he had been superintendent at Broadmoor for four years. The subject bristles with difficulty; medicine is everywhere involved in a controversial manner, while legal positions are often hard to appreciate. But Sullivan's treatment is fair as well as clear; his commonsense views were based on his scientific grasp of the problems, and his urbanity was due to a recognition of difficulties and not to any facile compromises.

Dr. Sullivan had been for a short time in delicate health, but the end came unexpectedly. He leaves a widow, herself an accomplished author, by whom he had one son.

## SUTHERLAND SIMPSON, M.D., D.Sc. EDIN.

THE death of Prof. Sutherland Simpson on March 3rd at his home at Ithaca, New York, ends a very remarkable career. Born in Orkney in 1863, Simpson left home whilst still fairly young and found his way south to Leith, where he answered an advertisement of Prof. William Rutherford's for a laboratory assistant in the department of physiology in the University of Edinburgh. His application was successful, and Prof. Rutherford soon discovered that his new assistant had ambitions and merits far beyond his position. Accordingly, Simpson was encouraged to attend classes at the Heriot Watt College in Edinburgh and very rapidly passed the preliminary examinations which qualified him to start on a scientific career. Next Rutherford made it easy for him to go to the University lectures, and in 1894 the laboratory assistant became a Bachelor of Science at the age of 31. With this success, however, he was by no means content. He asked permission to attend the medical courses, qualified in 1899, and in 1901 graduated as M.D., being awarded the gold medal for his thesis. In 1903 he became a Doctor of Science as well. And all this was achieved whilst Simpson was daily occupied in the laboratory and assisting the professor in his lectures. In the laboratory, of course, his status soon improved. He gained the Crichton Research Scholarship in Physiology, was elected Goodsir Memorial Fellow in Anatomy and Physiology, and, later, became lecturer in experimental physiology and assistant to the professor. During these Edinburgh days he found time for original work on secondary degeneration following injury to the cerebral motor cortex, on the pyramidal tracts, and on the regeneration of temperature. In the first decade of the twentieth century opportunities for young physiologists and pharmacologists presented themselves in colleges in the United States, and in 1908 Simpson was elected professor of physiology in the University of Cornell, a post he held until his death. There he gave himself up to teaching and research, and he and his pupils, amongst other contributions, published memoirs on the effects of excising the thyroid gland. Prof. Simpson married in 1908 Catherine G. P. Anderson, of Edinburgh.

## JOHN ALFRED SCOTT, M.D. DUB., F.R.C.S.I.

Dr. J. A. Scott, professor of physiology in the School of the Royal College of Surgeons in Ireland, who died on March 6th in his seventy-first year, was at work until the evening of his death. For the last year or two it had been clear that Dr. Scott was in failing health, but he sought no medical advice and worked hard.

John Alfred Scott was born in Dublin, and received his medical education at the Ledwich and Carmichael medical schools in that city. He qualified in 1881 and subsequently graduated in medicine at Dublin University; in 1886 he became a Fellow of the Royal College of Surgeons in Ireland. Soon after qualification he devoted himself to the study of physiology, and was appointed professor in the Carmichael School. In 1889, when the school was amalgamated with the school of the College of Surgeons, he became professor of physiology in the College, and he continued in this post to the day of his death. He was also for a long time pathologist to the Adelaide Hospital, and for some ten years acted as general secretary of the Royal Academy of Medicine in Ireland, contributing frequently to its communications. Prof. Scott was greatly interested in photography, and was an excellent photographer himself. Amongst his other interests was zoology, and for many years he was a member of the Council of the Royal Zoological Society of Ireland, being indefatigable in his work on behalf of the society and its gardens. As a teacher he was painstaking, clear, and forcible. He had the great gift of interesting his class, and he seemed able to enter into the difficulties of a student. His students came to love him as a friend who gave them unsparingly of his best.

# Parliamentary Intelligence.

## HOUSE OF COMMONS.

### WEDNESDAY, MARCH 3RD.

### *Mortality from Small-pox and Encephalitis Lethargica.*

Mr. COMPTON asked the Minister of Health to state what had been the percentage of mortality in the years 1924 and 1925 in small-pox and encephalitis lethargica, respectively.—Mr. NEVILLE CHAMBERLAIN replied: The case mortality rates—i.e., deaths per 100 notified cases, were: Small-pox, 0·35 per cent. in 1924 and 0·17 per cent. in 1925; encephalitis lethargica, 27·0 per cent. in 1924 and 50·0 per cent. in 1925 (The figures for 1925 relate to the first three-quarters of the year.)

### *Service Tuberculosis Cases and Insurance Benefit.*

Dr. VERNON DAVIES asked the Minister of Health if men invalided from the Army, Navy, or Air Force, suffering from pulmonary tuberculosis, were granted benefits under the National Health Insurance Act; and, if so, what were these benefits.—Mr. NEVILLE CHAMBERLAIN replied: All men serving in the forces of the Crown are insured under the National Health Insurance Act, and on discharge become entitled, subject to the ordinary conditions, to all the normal benefits of the Act—viz., medical, sickness, disablement, and maternity benefits. Further, any discharged man who has been for the necessary qualifying period a member of an approved society which provides additional benefits, becomes entitled to participate in such additional benefits. These additional benefits may take the form of an increase of the standard rates of sickness, disablement, and maternity benefits, or payment towards the cost of treatment of various kinds—e.g., dental, ophthalmic, hospital, or convalescent home treatment.

### *Small-pox and Vaccination.*

Mr. NUTTALL asked the Minister of Health the number of cases of small-pox reported in England and Wales since Jan. 1st last, and the number of non vaccinated persons who had contracted this disease.—Mr NEVILLE CHAMBERLAIN replied: During the seven weeks ended Feb. 20th, 1926, 2200 cases of small-pox were notified in England and Wales. Of these cases 1090 are stated to have been unvaccinated prior to infection by small-pox, while in 13 instances information as to the vaccinal condition is not yet available. These figures are subject to revision.

### *League of Nations Health Conference.*

Mr. TREVELYAN THOMSON asked the Minister of Health whether the English doctors who attended the conference of the commission of members of the Health Committee of the League of Nations at The Hague from Jan. 4th to the 7th to examine questions in connexion with small-pox, alastrim, and vaccinia, were present as representatives of the English Ministry of Health; and, if not, in what capacity were they there.—Mr. NEVILLE CHAMBERLAIN replied: This conference was convened by the Health Committee of the League of Nations. Sir George Buchanan attended in his capacity of British representative on that Committee. Dr. Gordon and Dr. Blaxall were invited by the Committee as experts possessing special knowledge and experience of the subjects to be discussed.

### *Geneva Opium Convention.*

Mr. CAMPBELL asked the Secretary of State for Foreign Affairs which of the powers had ratified the Opium Convention, which was signed at Geneva in February, 1925.—Sir AUSTEN CHAMBERLAIN replied: So far as H.M. Government are aware, no foreign power has yet ratified either the Opium Agreement or the Dangerous Drugs Convention, signed at Geneva on Feb. 11th and Feb. 19th, 1925, respectively. The British ratifications of the Agreement and Convention were deposited with the League of Nations on the 17th ultimo.

### THURSDAY, MARCH 4TH.

### *Cost of Tuberculosis Sanatoria.*

Dr. WATTS asked the Minister of Health the total amount expended on the provision of sanatoria for the treatment of tuberculosis in England and Wales; the annual cost of upkeep; the number of cases treated; and the percentage of cures claimed.—Mr. NEVILLE CHAMBERLAIN replied: The total capital expenditure incurred by local authorities in England and by the King Edward VII. Welsh National Memorial Association on the provision of residential institutions for the treatment of tuberculosis is approximately £1,100,000; the annual cost of the residential treatment of patients under the tuberculosis schemes of local authorities in England and Wales is approximately £2,312,000; and the average number of cases under treatment at any one time is approximately 18,850. As regards the last part of the question, I regret that no figures are at present available for the country as a whole, but I may refer my hon. friend to the report issued by the Medical Research Council (Special Report Series, No. 85) as to patients treated in the Frimley sanatorium.

### *National Health Insurance Report.*

Mr. RHYS DAVIES asked the Minister of Health whether it would be necessary to introduce legislation to give effect to any or the whole of the recommendations of the Royal Commission on National Health Insurance; and, if so, when it was intended to introduce such legislation.—Mr. NEVILLE CHAMBERLAIN replied: It would be necessary to introduce legislation to give effect to many, but not all, of the recommendations of the Royal Commission on National Health Insurance. I am not in a position to make any statement as to the introduction of such legislation.

### *Voluntary Hospitals Commission.*

Mr CAMPBELL asked the Minister of Health whether, in view of the decision of the Government not to adopt the recommendation of the Voluntary Hospitals Commission to provide, out of public funds, additional beds in voluntary hospitals, it was proposed to continue that Commission; and, if so, what duties remained for it to discharge.—Mr. NEVILLE CHAMBERLAIN replied: Yes, Sir. I have asked the Commission to continue their work both to act as a link between the Government and the voluntary hospitals, and also to keep in touch with the local voluntary hospital committees throughout the country and facilitate communication between them. The Commission will advise me on questions relating to voluntary hospitals, and will collect and circulate information likely to be of assistance to local committees, such as the circular on hospital construction now in course of preparation

### *Sterilisation of Milk.*

Lieut.-Colonel FREMANTLE asked the Minister of Health whether tubercle bacilli in milk were killed by sterilisation or pasteurisation as generally carried out; and whether he was aware of any means of killing tubercle bacilli in milk other than by sterilisation or pasteurisation.—Mr. NEVILLE CHAMBERLAIN replied: I am advised that pasteurisation carried out in accordance with the procedure laid down in the Milk (Special Designations) Order confers a very substantial protection against infection by tubercle bacilli. It is probable that the process commercially described as sterilisation affords similar protection, and that this is true in a smaller degree of other methods of treating milk by heat. I am not aware of any other practicable means of killing tubercle bacilli in milk.

Colonel FREMANTLE asked the Minister of Health the proportion of milk estimated to be tuberculous from analysis of samples in London, Birmingham, Manchester, Edinburgh, Leeds, Liverpool, Plymouth, Cardiff, Hull, and Newcastle, respectively.—Mr NEVILLE CHAMBERLAIN replied: So far as the question relates to Edinburgh it should be addressed to my right hon. friend the Secretary for Scotland. The following is a statement of the number of samples of milk taken in certain towns in England and Wales during 1924 for examination for tubercle bacilli and number found to be tuberculous:—

| Place. | Samples taken. | Samples tuberculous. | Percentage tuberculous. |
|---|---|---|---|
| London (City) .. | 39 | 5 | 12·8 |
| London (County) .. | 2400 | 121 | 5·0 |
| Birmingham .. | 303 | 26 | 8·6 |
| Manchester | 590 | 48 | 8·1 |
| Leeds .. | 68 | 1 | 1·5 |
| Liverpool .. | 781 | 79 | 10·1 |
| Plymouth .. | 11 | 2 | 18·2 |
| Cardiff.. .. | 53 | 1 | 1·9 |
| Kingston upon Hull .. | 18 | nil. | nil. |
| Newcastle-upon-Tyne | 220 | 7 | 3·2 |
| — | 4483 | 290 | 6·5 |

### *Mental Deficients and Assaults on Children.*

Mr. BRIANT asked the Minister of Health if his attention had been called to the case of a lad of 17 who was mentally deficient and was charged at Stratford, E., police-court with an assault on a child of five; if he was aware that the same lad was charged with a similar offence on a previous occasion but, owing to the failure to find a suitable home, was discharged; and if he would see that sufficient homes were provided for these cases so that deficients who were a danger to children should not be allowed to repeat their offences.—Mr. NEVILLE CHAMBERLAIN replied: The answer to the first two parts of the question is in the affirmative. In regard to the latter part of the question, I have already informed the Board of Control that they should press local authorities to fulfil their duty under the Mental Deficiency Act of providing suitable and sufficient accommodation for mental defectives ordered to be sent to institutions. As regards the particular case, the Board of Control have agreed, in the exceptional circumstances, that if the court orders this youth to be sent to an institution, he can be received into the State institution at Rampton, which has been provided for mental defectives of dangerous or violent propensities.

### *Approved Societies and Convalescent Treatment.*

Mr. Briant asked the Minister of Health if, in considering the distribution of surpluses of approved health societies, he would take into account the necessity of the provision of sufficient convalescent homes and the granting of full maintenance allowances for the families dependent on the sick persons, so as to ensure that the patients took full advantage of convalescent treatment till full recovery was reached.—Mr. Neville Chamberlain replied: It rests with each approved society having a disposable surplus on valuation to decide what additional benefits are to be provided for its members out of that surplus. Among such benefits are included the provision and maintenance of premises suitable for convalescent homes, and the payment of the whole or part of the cost of maintenance and treatment of members in convalescent homes, the latter of which is one of the most widely adopted benefits. I am satisfied that societies generally are fully alive to the advantages of convalescent home treatment. There is no provision in the Act for the payment of maintenance allowances for the dependants of sick persons, but while an insured person is being maintained in a convalescent home he would ordinarily be entitled also to sickness or disablement benefit, which would be available towards the cost of the maintenance of his dependants.

### *Industrial Accidents in 1925.*

Lord Henry Cavendish-Bentinck asked the Home Secretary the total number of industrial accidents, fatal and non-fatal, reported during 1925.—Sir William Joynson-Hicks replied: The total number of persons reported as killed during 1925 by industrial accidents in factories, docks, and other premises under the Factory Acts, in mines and quarries, and in the railway service, was 2471. The number reported as injured by accidents on premises under the Factory Acts was 158,778. The figures as to non-fatal accidents in the other industries mentioned are not yet available, and the figures just given are provisional.

## FRIDAY, MARCH 5TH.

### *Physical Defects of Naval Recruits.*

Mr. Hore-Belisha asked the First Lord of the Admiralty what percentage of applicants was rejected for the Navy in the years 1910, 1911, 1912, 1913, and 1925; and what the principal physical defects were, giving the proportions to the total number of rejections.—Mr. Davidson replied: Statistics as regards rejections for physical defects are not available for the years 1910 to 1913. The percentage rejected in 1925 was 37, and of the candidates rejected by the final medical examining officers the principal defects were:

| Defect. | Proportion to total of rejections. |
|---|---|
| Defective vision .. .. .. .. | 19·39 per cent. |
| Defective teeth .. .. .. .. | 12·66 „ |
| Disease of heart .. .. .. .. | 8·75 „ |
| Flat-foot .. .. .. .. | 8·41 „ |
| Disease of ears .. .. .. .. | 7·61 „ |

The preparation of similar statistics for candidates who were not sent to the final medical examining officers would involve an expenditure of clerical work which I do not think would be justified.

### *Medical Adviser at the Colonial Office.*

Mr. Walter Baker asked the Secretary of State for the Colonies whether he was now in a position to state his decision regarding the proposal to appoint a medical director in the Colonial Office to act as a liaison officer between the Crown Colonies and the Civil Research Committee.—Lieut.-Colonel Headlam asked a similar question.—Mr. Amery replied: I propose at an early date to appoint in the Colonial Office a chief medical adviser whose duty it will be to advise me on all medical and health questions and to see that all important information bearing on these matters is collected and circulated.

### *Deaths from Infectious Diseases.*

Mr. Whiteley asked the Minister of Health how many deaths from influenza, measles, diphtheria, scarlet fever, and enteric fever were registered in the year 1925.—Mr. Neville Chamberlain replied: Reliable figures are not yet available, but the provisional figures derived from the Registrars' Quarterly Returns, are as follows:

| Disease. | Provisional No. of deaths registered in England and Wales, 1925. |
|---|---|
| Influenza .. .. .. .. .. | 12,587 |
| Measles .. .. .. .. .. | 5,221 |
| Diphtheria .. .. .. .. | 2,716 |
| Scarlet fever .. .. .. .. | 981 |
| Enteric fever .. .. .. .. | 373 |

Mr. Whiteley asked the Minister of Health whether he would state the provisional number of cases of diphtheria, scarlet fever, chicken-pox, pneumonia, enteric fever, small-pox, and encephalitis lethargica notified during the year 1925.—Mr. Neville Chamberlain replied: The figures asked for, with the exception of those for chicken-pox, which is not universally notifiable, are as follows:

| Disease. | Provisional No. of cases in England and Wales, 1925. |
|---|---|
| Diphtheria .. .. .. .. | 47,723 |
| Scarlet fever .. .. .. .. | 91,357 |
| Pneumonia .. .. .. .. | 55,960 |
| Enteric fever .. .. .. .. | 2,779 |
| Small-pox . .. .. .. .. | 5,363 |
| Encephalitis lethargica .. .. .. | 2,637 |

## MONDAY, MARCH 8TH.

### *Restrictions on Opium Production in India.*

Mr. Campbell asked the Under Secretary of State for India what new policy had been propounded by the Government of India in regard to the production and export of Indian opium.—Earl Winterton replied: In opening the Council of State on Feb. 9th the Viceroy made the important announcement that the Government of India intends, subject to the approval of the legislature, to reduce progressively the export of opium to all destinations so as to extinguish the trade altogether within a definite period except for strictly medical purposes. This policy would involve a corresponding reduction in the amount of opium produced. The period within which extinction will take place has not yet been fixed, and the position of the cultivators is one of the factors that must be taken into account in defining it. The new policy, if approved by the Indian legislature, would go far beyond the international obligations of India, and the Government of India, in proposing it, have been animated by a determination to do all in their power to coöperate to secure that improvement in the world opium situation which was looked for as a result of the Geneva Conference.

### *Air Force Medical Services.*

The votes for personnel, pay, stores, buildings, and land in connexion with the Royal Air Force were considered on report.

Mr. Basil Peto said that he had been looking into the separate medical staff of the Air Ministry. He found that the total of the medical staff was 1377, and the gross cost was £347,500, or, deducting all that was allowed for the part of the medical staff that was paid for under other Ministry votes, it was £209,000 net. The real figure, of course, was £347,500, and the 1377 members of the medical staff worked out at one for every 26 of the whole personnel of the Air Service in Vote A. There were only 920 flying and observer officers this year, or 134 less than last year, and the 1377 medical staff seemed to compare very unfavourably with the total number of flying and observer officers.

Sir Samuel Hoare (Secretary of State for Air) said that they were trying, even with the existence of the three Services—the Army, Navy, and the Air Force—to reduce overlapping to the lowest possible limit. [Sir F. Wise: "Hospitals."] They did not want to set up hospitals anywhere where Army and Navy hospitals were providing treatment for Air Force officers and men. To-day, in England, there were only three Air Force hospitals. In each case these were provided where there were no other facilities for the officers and men of the Air Force in the near neighbourhood. There were two hospitals for men and one hospital for officers. In Iraq, where the command was an Air Command, and where the main responsibility was an Air Ministry responsibility, there were no Army hospitals, and the Air Force hospital in Iraq was doing all the work for the British and Indian battalions. He would like to see the arrangement pushed and developed to the full.

In the previous debate a few days ago Lieut.-Commander Kenworthy had twitted the Air Ministry about a dental service. They had no dental service at all. They used the dental officers of the Royal Army Medical Corps. Right through the whole field of common service it was their definite policy, and he could not emphasise that too much, to avoid duplication wherever they could.

Capt. Crookshank said that the House was extremely gratified to hear the promise of the Secretary of State to look into the matter of the doctors and the nurses. Naval nurses did not go to the sea in ships, and air nurses did not go into the air. Why should they not be brought from a common school?

The votes were agreed to.

# Medical News.

UNIVERSITY OF OXFORD.—The Weldon Memorial prize has been awarded to Dr. Major Greenwood. The prize is given once every three years to the person who has published, during the past six years, the most noteworthy contribution to biometric science.

MEDICO-LEGAL SOCIETY.—A meeting will be held at 11, Chandos-street, Cavendish-square, London, W., on Tuesday, March 16th, at 8.30 P.M., when Dr. Knyvett Gordon will read a paper on Fur Dermatitis.

HARVEIAN SOCIETY.—An ordinary meeting of this society will be held at Paddington Town Hall on Thursday, March 18th, at 8.30 P.M., when there will be a discussion on the Use of Ultra-violet Rays in Medicine and Surgery, to be opened by Dr. Leonard Hill, followed by Dr. W. T. O. Pugh.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.—On March 26th a meeting is to be held at 11, Chandos-street, London, W., at 8.30 P.M., when Dr. George Riddoch and Dr. P. Panton will contribute papers on Marriage and Syphilis. Consideration of this subject will be resumed at the same hour on April 30th, when the speakers will be Dr. Lacapere and Dr. R. C. Jewesbury.

CONFERENCE ON MATERNITY AND CHILD WELFARE. The fourth English-speaking conference on Maternity and Child Welfare is to be held, in connexion with the National Baby Week celebrations, at the Caxton Hall, Westminster, from July 5th–7th. The main subjects of discussion will be the care of the toddler, the care of the mother (expectant, at confinement, nursing, postnatal), and the father's part in the child welfare movement. There are to be lectures, film displays, an exhibition, social functions, and visits to child welfare institutions. Applications for tickets should be addressed to the hon. secretary, National Association for the Prevention of Infant Mortality, Carnegie House, 117, Piccadilly, London.

SCHOLARSHIPS AND GRANTS FOR SCIENTIFIC RESEARCH.—The Council of the British Medical Association is prepared to receive applications for an Ernest Hart Memorial Scholarship of £200 per annum, for the study of some subject in the department of State Medicine, and for three research scholarships, each of £150 per annum, for research into some subject relating to the causation, prevention, or treatment of disease. Each scholarship is tenable for one year, from Oct. 1st, 1926. A scholar may be reappointed for not more than two additional terms, and may hold a junior appointment at a university medical school or hospital, provided that the duties do not interfere with his work as a scholar. The Council will also receive applications for grants for the assistance of research into the causation, treatment, or prevention of disease. Preference will be given, other things being equal, to members of the medical profession and to applicants who propose as subjects of investigation problems directly related to practical medicine. Applications for the scholarships and grants must be made in proper form before June 5th. The conditions of their award are stated in the regulations, which may be had from the Medical Secretary, British Medical Association House, Tavistock-square, London, W.C. 1

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Mr. H. W. Carson will lecture for the Fellowship on Hernia on Thursday, March 18th, at 5 P.M., in the lecture hall of the Medical Society, 11, Chandos-street, London, W. This lecture will be free to members of the medical profession. From March 15th to 27th the Brompton Hospital will hold an all-day course dealing with various forms of pulmonary diseases by demonstration, lecture, and operation. At the London School of Hygiene and Tropical Medicine demonstrations will be given twice weekly in the afternoons by Dr. G. C. Low and Dr. P. H. Manson-Bahr, from March 16th, for four consecutive weeks. For the convenience of general practitioners the Hampstead General Hospital has organised an afternoon course (4.30 to 6) to cover systematic teaching in all departments. From April 14th to May 5th Dr. C. B. Heald will give four lecture-demonstrations at the Royal Free Hospital on successive Wednesdays at 5.15 P.M. on the Recent Advances in Medical Electrical Treatment. An intensive post-graduate course in proctology is to be given at St. Mark's Hospital from April 19th to 24th. Sessions will be from 10.30 A.M. to 6 P.M. daily, including Saturday. Early application is requested, as the course will not be given unless ten entries are received by April 12th. Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal*, may be had on application to the Secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

ROYAL FREE HOSPITAL EXTENSION.—A new wing is to be added at an estimated cost of £50,000.

KING'S COLLEGE HOSPITAL.—It is intended during the year to open another ward containing at least 21 beds. The beds available for general patients now number 267 out of a total of 388, but 63 are available for paying patients.

SOCIETY FOR THE STUDY OF INEBRIETY.—The annual meeting of this society will be held at 11, Chandos-street, Cavendish-square, London, W., on Tuesday, April 13th, at 4 P.M. After the election of officers Sir William Willcox will open a discussion on the Prevention and Arrest of Drug Addiction.

THE LATE MR. W. PERMEWAN.—We regret to announce the death on March 9th, at Liverpool, at the age of 61, of Mr. William Permewan, consulting surgeon to the Royal Southern Hospital, and lecturer in laryngology in the University of Liverpool.

NORTH-WESTERN TUBERCULOSIS SOCIETY.—A meeting of this society will be held in the surgical theatre of the Medical School, Liverpool, on Thursday, March 18th, at 8 P.M., when Dr. J. G. Adami, the Vice-Chancellor of the University, will read a paper. Medical practitioners and students are cordially invited.

LONDON HOSPITAL MEDICAL COLLEGE.—The *Hutchinson Triennial Prize of £60* will be awarded to a qualified student of the London Hospital, who has been registered for not more than 10 years, for a dissertation on Suppuration in the Lungs and Pleura, to be sent in not later than March 31st, 1929.

ST. MARY'S HOSPITAL, PADDINGTON.—A "Pound Day" will be held on March 18th, when Princess Marie Louise will receive purses at 3.30 P.M. Members of the Ladies Association will be at the hospital on March 17th and 18th, from 9 A.M. to 7 P.M., to accept gifts in kind. Cheques or money may be sent to Mrs. Wilfred Harris, 50, Wimpole-street, London, W. 1.

DISTRICT NURSING IN LONDON.—The Central Council for District Nursing in London reported at its annual meeting that in the Administrative County of London there is one district nurse for every 18,120 of the population. No further provision can be made at present owing to lack of money, but extensions are taking place in Greater London.

CHELSEA CLINICAL SOCIETY.—A meeting of this society will be held on Tuesday, March 16th, at 8.30 P.M., at the Florence Restaurant, Rupert-street, London, W., when there will be a discussion on Spa Treatment. Amongst the speakers will be Dr. W. Edgecombe, Dr. Malcolm Campbell, Dr. Matthew B. Ray, Dr. Violle (Vittel), Dr. Debidour (Mont d'Or), and Dr. Ferreyrolle (La Bourboule). Dinner will be served at 7.30 P.M., before the meeting.

ROYAL INSTITUTE OF PUBLIC HEALTH.—A congress will be held at Bristol from May 19th to 24th (Whitsuntide). An interesting and varied programme has been prepared; the railway companies have agreed to reduce the fares of those attending the congress, and hotel or boarding-house accommodation can be arranged for early applicants. Information may be had from the hon. secretary of the Royal Institute, 37, Russell-square, London, W.C. 1.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society will be held at 1, Upper Montague-street, Russell-square, London, W.C., on Friday, March 19th, when there will be a discussion on Cancer from the point of view of: (*a*) public health administration (Dr. W. D. Champneys); (*b*) the surgeon (Prof. G. E. Gask); (*c*) the research worker (Dr. W. D. Newcomb); (*d*) the general practitioner (Dr. F. E. Allen). Others who will take part in the discussion are Mr. C. J. Bond and Lieut.-Col. A. B. Smallman (Ministry of Health). The President (Dr. G. F. Buchan) will take the chair at 5 P.M., and the meeting will be open to any member of the profession.

THE LATE DR. LEIGH COX.—Dr. Wilfred Leigh Cox, who died on Feb. 28th of blood poisoning after a ten day's illness, came of a family with a medical tradition. His father is Dr. Percy Cox, of Ealing, and his grandfather practised in Manchester. Dr. Cox, who was only 38 years of age, was born at Bowdon in Cheshire, and studied at Manchester and the Middlesex Hospital, where he qualified in 1915. In the early days of the war he was attached to the Anglo-French American Hospital in Paris. Returning to England in 1916, he offered his services again to the R.A.M.C., but was refused on account of ill health. He freed another medical man for war service and was granted an hon. commission in the R.A.M.C. When the war was over Dr. Cox settled in practice at Southbourne, Hampshire, where he earned a high reputation. His funeral, on March 3rd, was attended by a large gathering of friends.

James Mackenzie Institute for Clinical Research.—A post-graduate course of 50 lectures and demonstrations for general practitioners will be held at the Institute, St. Andrews, from June 14th to 30th. Particulars may be had from the Secretary.

Nottingham Medico-Chirurgical Society.—On Feb. 18th Dr. Leonard Williams read a paper on Endocrinology and Old Age, and on Feb. 25th Sir George Newman addressed the Society on the Relation of the State to Medicine.

Hospital, Health, Nursing, and Midwifery Exhibition and Conference.—A section dealing exclusively with the work of voluntary organisations is to be included at the annual conference and exhibition to be held from April 12th to 16th, from noon till 8 p.m. daily, at the Central Hall, Westminster.

Course in Hospital Administration. — Dr. E. W. Goodall, medical superintendent, will begin a course on hospital administration at the North-Western Hospital, Metropolitan Asylums Board, on April 8th. The course, which is designed for candidates for the D.P.H. and will include clinical instruction in infectious fevers, will continue for three months, on Mondays and Thursdays at 1.15 p.m. and on alternate Saturdays at 10.30 a.m.

British Social Hygiene Council. — A new quarterly review called *Health and Empire*, published for the Council by Constable and Co., is to appear this month, and will appeal to the public as well as to medical and social workers. It will describe experiments in educational methods, and its aim is to correlate new developments in psychology, biology, and physiology with special social problems.

Home for New Health Society.—Mrs. Henry Allhusen, late of Stoke Court, Stoke Poges, has given £4000 to establish a National Home of Health as the head-quarters of the New Health Society. The gift is made so that the society's central offices shall be "a lasting memorial to her husband and her children, Harry and Elizabeth, in the hope that the work of the society, in its teachings of the laws of health to the public, will preserve the lives of others equally dear to their relatives and friends."

Distribution of Insulin by Local Authorities. The Scottish Board of Health has sent out circulars to local authorities reminding them that they are now empowered to provide insulin for diabetics in their areas who cannot afford to buy it for themselves. Many authorities have, in fact, long been making this provision, and the powers now conferred by the Public Health (Scotland) Amendment Act, 1925, retrospectively cover such arrangements as they may have made since March 1st, 1921, subject to the approval of the Board of Health. Cost has hitherto been a serious consideration in the progress of these schemes, and the board has now made arrangements with manufacturers whereby local authorities can get their insulin at reduced rates. The special price fixed is 2s. per 100 units, plus postage; this arrangement applies to the insulin sold by Boots Pure Drug Co., Ltd., British Drug Houses, Ltd., and Burroughs, Wellcome and Co. Local authorities who want to get their insulin at this rate are asked to send their orders to the Board, stating the quantity and make of insulin required. The orders will then be sent on to the manufacturers, who will forward the insulin direct, but will send their account to the Board. Every six months the Board will send on the total account to the local authority.

The late Dr. F. J. Tresilian.—Dr. Frederick James Tresilian, who died after a short illness at Enfield on Feb. 14th, at the age of 61, came of the Cornish family Tresilian of that ilk. He was brought up in Ireland and was educated at Midleton College and Queen's College, Cork, where he graduated as M.D. and M.Ch. in 1885. Two years later he became M.R.C.P. Edin. and for some time acted as assistant to a doctor in Wales. In 1890 he joined Dr. Briand in practice at Enfield, and from 1891 until quite recently worked without assistance there. In his early days at Enfield he also acted as clinical assistant at the ear, nose and throat, and eye departments at the Prince of Wales's Hospital, Tottenham, and also at the Central London Ear, Nose and Throat Hospital. In 1902 he became F.R.C.P. Edin. Dr. Tresilian was a keen and energetic member of the British Medical Association and of the North-East London Clinical Society. He was a medical referee of the Prudential Assurance Company and for many years served as honorary medical officer to the Enfield War Memorial Hospital. At his funeral a remarkable tribute was paid to his memory by a large gathering of those who had reason to admire him and regret his death. Dr. Tresilian leaves a widow, two daughters, and a son. His elder daughter belongs to the medical profession.

Mental After-Care Association.—The annual meeting will be held on Tuesday, March 16th, at 3 p.m., at the Fishmongers' Hall, London Bridge, E.C., when Sir Charles C. Wakefield, the President, will take the chair, and the following will speak: Sir William Collins, M.D., Dr. Nathan Raw, Mr. Lionel Faudel Phillips, Capt. A. O. Goodrich, Sir Maurice Craig, M.D., Dr. R. Percy Smith, and Dr. R. C. Turnbull. Members of the public are invited to be present, and information can be obtained from the secretary, Miss Vickers, Church House, Westminster, S.W. 1.

Leeds Workpeople's Hospital Fund.—This fund has contributed upwards of half a million pounds to medical charities in the city and district since it was started 40 years ago. The sum collected in 1925 was a new record in its history. The contributions reached over £42,000, most of which was raised by weekly collections of workers' pennies in the factories, workshops, and foundries of the city. The principal grants were £21,500 to the Leeds General Infirmary, £3225 to the Public Dispensary, £2687 to the Hospital for Women and Children, £1075 to the Maternity Hospital, £860 to the District Nursing Association, and £335 to the Jewish Hospital. The fund also maintains three convalescent homes, two for women and one for men, for the use of workers whose health has failed. The cost of their maintenance last year was £8240.

Royal Medical Benevolent Fund Guild.—The annual meeting was held on Feb. 27th at 47, Brook-street, Lady Bland-Sutton presiding over a very large assembly of subscribers and their friends. Lady Fripp, chairman of the council, reported a great increase in activity, necessitating the appointment of a general secretary-accountant to replace Miss Thomson, whose resignation after 15 years' zealous work was deeply regretted. Reports were given of the development of the various provincial branches of the Guild, some of which, notably Edinburgh, Bath, Cardiff, Glasgow, Reigate and Redhill, and Preston, had made good progress in obtaining new subscribers or in raising funds by means of entertainments or sales. A new branch had been formed at Great Yarmouth. Among the London districts Hampstead and St. Pancras were prominent, and five new districts had been formed—North London, Harrow, Pinner, Barnes, and Mortlake. In the unavoidable absence of Mrs. Scharlieb, M.D., the report of the hon. treasurer was read by Lady Bradford. She said that though donations this year had amounted to the record total of £3753, the amount (£1288) derived from regular annual subscriptions—which formed the only really reliable source of income—did not meet the often inadequate help given to older beneficiaries, quite apart from the money required for educational grants. The case committee had appealed for a 50 per cent. increase in the monthly maintenance grants to the older beneficiaries, and new subscribers were urgently needed to this end. Mrs. A. Ormond, chairman of the case committee, in a moving report of the cases relieved, gave examples of the benefits conferred on the younger persons—from a grant to enable a girl left fatherless to complete her medical studies, to the provision of one square meal per day to a lad apprenticed to a firm of engineers. During 1925 21 girls and 16 boys had been educated entirely or partially at the cost of the Guild. Observation of children living in homes where money is pitifully short has convinced the committee that where possible boarding schools are to be preferred. The depressing atmosphere of such homes, a too limited and monotonous diet, and the absence of any money even for trivial amusements such as bus rides, are bad for children, and the care-free atmosphere of school life is much more desirable. Mr. Pett Ridge and Miss Madge Titheradge spoke eloquently on behalf of the Guild, and cordial votes of thanks were given to Sir John and Lady Bland-Sutton and to the officers of the Guild. At the invitation of the Medical Insurance Agency, which has this year again presented a donation of £525, a representative of the Guild, in the person of Mrs. A. Ormond, has been appointed to serve on the subcommittee of the agency dealing with the education of girl beneficiaries. Legacies received during the year include £100 from the late Miss E. J. Humby, £200 from the George Macbain Trust, and £300 from the late Miss Constance Turner. The Stock Exchange Male Voice Choir again in 1925 and in 1926 devoted the proceeds of their annual concert to the Guild, and in 1925 the sum accruing from the third of the successful golf competitions organised by Lady Rigby, under the auspices of the Ladies' Medical Golfing Society, completed the £250 for an annuity scholarship which these competitions were started to provide. Special efforts such as these are of value not only for the money they bring in but for the interest they excite in those previously unfamiliar with the work of the Guild. Those who are prepared to help in propaganda work in any form, or to send parcels of old clothes, are asked to communicate with the Secretary of the Guild, 58, Great Marlborough-street, London, W.

OXFORD OPHTHALMOLOGICAL CONGRESS.—The Congress will assemble at Keble College on the evening of Wednesday, July 14th, and the meeting will be held on July 15th, 16th, and 17th. On July 15th there will be a discussion on Sympathetic Ophthalmia, to be opened by Mr. Malcolm L. Hepburn, Mr. S. H. Browning, and Dr. T. Harrison Butler. The Doyne memorial lecture will be delivered on July 16th, by Dr. Thomson Henderson, on the Anatomy and Physiology of Accommodation in Mammalia. One afternoon will be devoted to demonstrations in the scientific and commercial museums. Further information may be had from the hon. secretary at Salisbury House, Wolverhampton.

DR. J. B. HURRY'S GIFTS TO READING.—Dr. J. B. Hurry, the author of "Vicious Circles in Disease," which has been translated into French, Spanish, and Italian, and has gone through three editions in this country, is leaving Reading for Bournemouth after 40 years of active interest in the town both as a medical man and, quoting the farewell words of the mayor, "one of Reading's best citizens." Dr. Hurry has given the town as a parting gift the last of a series of ten pictures illustrating the history of Reading Abbey, which he has had painted with the object of stimulating civic pride and local patriotism. The last picture has been painted by Mr. Stephen Reid and shows the Parliament of Henry VI. at Reading Abbey, A.D. 1453. The ten pictures are housed in the Reading Art Gallery and make a collection which is perhaps the only one of its kind in this country. The presentation ceremony took place in the Council Chamber of the Reading Municipal Buildings on March 6th. The nine pictures already presented to the town are as follows: The Burial of Henry I., Founder of the Abbey, 1136 (Artist, Harry Morley). The Trial by Combate between Henry of Wessex and Robert of Montfort, 1163 (Harry Morley). The Hallowing of the Abbey Church by Archbishop Thomas Becket, 1164 (Stephen Reid). The Visit of Heraclius, Patriarch of Jerusalem, to Henry II., 1185 (Stephen Reid). "Summer is I-cumen in," Circa, A.D. 1240 (E. Board). The Marriage of John of Gaunt to Blanche of Lancaster 1359 (E. Boardman Wright). The Election by the Abbot, John Thorne I., of Thomas Clerke to be Mayor of Reading, 1460 (Stephen Reid). The Enthronement of Elizabeth Woodville as Queen of Edward IV., 1464 (E. Board). The Execution of Hugh Faringdon, the last Abbot of Reading, 1539 (Harry Morley).

SUSSEX THROAT AND EAR HOSPITAL.—A good financial position was reported by the governors at the recent annual meeting at Brighton, and it is hoped that the new out-patients' department will be begun this year. During 1925 233 more in-patients were treated at the hospital, the total being 902, and the number of out-patients increased by 217 to 1858. Contributions paid voluntarily by patients amount to nearly £1000, of which over £935 came from in-patients. The hospital has now the support of the Brighton, East Sussex, West Sussex, and Lewes education committees, and also continues to have the support of the Sussex Provident Scheme.

## NFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 27TH, 1926.

*Notifications.*—The following cases of infectious disease ere notified during the week:—Small-pox, 202 (last week 12); scarlet fever, 1792; diphtheria, 1214; enteric fever, 3; pneumonia, 1300; puerperal fever, 72; cerebro-spinal ver, 10; acute poliomyelitis, 5; encephalitis lethargica, 4; continued fever, 2; dysentery, 11; ophthalmia onatorum, 100. There were no cases of cholera, plague, r typhus notified during the week.

Of the 203 cases of small-pox (50 more numerous than in e previous week) 48 were reported from the county of erby, 38 of these from Derby C.B.; 157 (last week 124) om the county of Durham, 11 being from Gateshead C.B., 5 from South Shields C.B., the remainder from widely cattered urban and rural districts, and including 31 (last eek 35) from Blaydon, 14 from Chester-le-Street, and 11 om Houghton-le-Spring; 4 from the county of Lancaster, 3 at Oldham C.B., a new focus; 43 from the county of orthumberland, 28 of these from Ashington; 3 from the ounty of Nottingham; 6 from the East Riding of Yorkshire Kingston-upon-Hull 1); 32 from the West Riding, 23 of hese being from Rawmarsh and 5 from Rotherham R.D.

*Deaths.*—In the aggregate of great towns, including London, here were 3 (2) deaths from enteric fever, none from small-ox, 105 (47) from measles, 7 (3) from scarlet fever, 57 (4) om whooping-cough, 56 (13) from diphtheria, 40 (11) from iarrhoea and enteritis under 2 years of age, and 69 (20) om influenza. The figures in parentheses are those from London itself. For the fourth time during the last six eeks the deaths from measles exceeded 100. The mortality om influenza remains practically stationary.

# Medical Diary.

## SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

*TUESDAY, March 16th.*—*5.30 P.M., GENERAL MEETING OF* FELLOWS. 8.30 P.M., PATHOLOGY. Annual General Meeting. Election of Officers and Council for 1926–1927. *Papers:* Dr. Paul Fildes: Observations on Tetanus. Sir Lenthal Cheatle: Paget's Disease of the Nipple and Changes in the Underlying Breast. Dr. James Young: Further Study of the Micro-Parasite Isolated from Carcinoma by Young, Glover and Colleagues, Stearn, Sturdivant and Stearn, and others.

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. *Papers:* Sir StClair Thomson: Antimonial Cups. Mrs. Lindsay: Dentistry in the Eighteenth Century.

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) *Cases:* Dr. S. E. Dore: (1) Xanthoma Tuberosum Multiplex. (2) Gaucher's Disease with Cutaneous Lesions (with Dr. de Wesselow). Other cases will be *shown.*

FRIDAY.—8.30 P.M., ELECTRO-THERAPEUTICS. *Paper:* Dr. R. O. Moody (California): The Normal Position of the Abdominal Viscera and Enteroptosis.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, March 15th.—9 P.M., Dr. E. Farquhar Buzzard: Principles of Treatment in Relation to Diseases of the Nervous System (Third Lettsomian Lecture.)

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THURSDAY, March 18th.—8.15 P.M. A Laboratory Meeting at the Royal Army Medical College, Grosvenor-road, Millbank, S.W. *The following, amongst others, will* give demonstrations: Prof. Warrington Yorke (on behalf of Prof. Blacklock), Dr. P. A. Buxton, Colonel Clayton Lane, Colonel W. P. MacArthur, Dr. A. C. Stevenson, Drs. J. G. Thomson and A. Robertson, Drs. C. M. Wenyon and H. H. Scott.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, March 16th.—5 P.M., Dr. Bernard Hart: Development of Psychopathology, and its Place in Medicine (second Goulstonian Lecture).

THURSDAY.—5 P.M. (last Goulstonian Lecture).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn fields, W.C.

MONDAY, March 15th.—5 P.M., Mr. Shattock: Some Bone Tumours.

FRIDAY.—5 P.M., Sir Arthur Keith: Hydrocephaly and Encephalocele.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, March 15th, to SATURDAY, March 20th.—Fellowship of Medicine lecture, at the Medical Society, 11, Chandos-street, W. Thursday, at 5.30 P.M., Mr. H. W. Carson: Hernia. Free to all members of the medical profession.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Post-graduate Course in *Gynæcology.* Daily operations, lectures, and demonstrations.—HAMPSTEAD GENERAL HOSPITAL, Haverstock-hill, N.W. Two weeks' course, 4.30 to 6 P.M., for Practitioners. Demonstrations, &c., in various departments of the Hospital throughout the course.—*HOSPITAL FOR* DISEASES OF THE CHEST, Brompton. All-day course *for two weeks.* Operations, lectures, and demonstrations from 10.30 A.M.—LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Endsleigh-gardens, N.W. Tuesday and Thursday, 2 P.M., Dr. Low and Dr. Manson Bahr. Special lecture-demonstration, illustrated by cases in *hospital. Further information from the* Secretary of the Fellowship of Medicine.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: FEBRUARY–MARCH, 1926.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, March 15th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Mental Deficiency: Dr. Birley.

TUESDAY, March 16th.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Cerebral Vascular Disease, I.: Dr. Adie.

THURSDAY, March 18th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Epilepsy: Dr. Martin.

FRIDAY, March 19th.—2 P.M., Out-patient Clinic: Dr. Adie. 3.30 P.M., The Cerebro-spinal Fluid in Meningitis: Dr. Greenfield.

The fee for the Course, including Pathology lectures, is £5 5s. For those who hold Perpetual Tickets the fee is £3 3s.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the *Office on entering for the Course.*

J. G. GREENFIELD, Dean of Medical School.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Monday, March 15th.—10 A.M., Surgical Out-patients: Mr. W. E. Tanner. 10.30 A.M., Gynæcological Operations: Mr. A. E. Giles: Throat, Nose and Ear Operations: Mr. W. Ibbotson. 2 P.M., Medical, Surgical, and Gynæcological Clinics, Operations. 6.30 P.M., Venereal Department.

Tuesday.—2 P.M., Medical, Surgical, Throat, Nose and Ear Clinics, Operations. 4.30 P.M., Dr. J. B. Alexander: Rheumatoid Arthritis.

Wednesday.—10.30 A.M., Surgical Operations: Mr. E. Gillespie. 2 P.M., Medical, Eye, and Skin Clinics, Operations. 5.30 P.M., Venereal Department.

Thursday.—10.30 A.M., Dental Out-patients: Mr. E. S. Pierrepont. 2 P.M., Medical Surgical, and Throat, Nose and Ear Clinics, Operations. 5 P.M., Operations.

Friday.—10.30 A.M., Eye Operations: Mr. N. Fleming. 2 P.M., Surgical, Medical, and Children Clinics, Operations. 3 P.M., Gynæcological Clinic. 6.30 P.M., Venereal Department.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

Friday, March 19th.—4 P.M., Dr. Nicol Rankin: Purulent Rhinitis.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, March 18th.—4 P.M., Mr. Barrington-Ward: Empyema.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

Tuesday, March 16th.—5 P.M., Dr. Haldin-Davis: Leukæmia Cutis. Mycosis Fungoides.

Thursday.—5 P.M., Dr. Ingram: Pathological Demonstration. (Chesterfield Lectures.)

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

Friday, March 19th.—3.30 P.M. (at the Royal Hospital). Dr. Abercrombie: Types of Paralysis in Childhood and their Treatment.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

Tuesday, March 16th.—4.15 P.M., Dr. W. Fletcher Shaw: Hæmorrhage about the Menopause.

Friday.—4.15 P.M., Mr. P. R. Wrigley: Demonstrations of Surgical Cases.

# Appointments.

Douglas, Charlotte A., M.D. Glasg., has been appointed Medical Officer to the Scottish Board of Health.

Gilmore, Edward R. W., M.B., Ch.B., D.P.H. Vict., D.P.H. Lond., D.T.M. Liverp., Assistant Medical Officer of Health for the County Borough of Southampton.

Hunter, A. E., M.D. Edin., one of the Medical Referees under the Workmen's Compensation Act for the Falkirk District.

Mitchell, Godfrey W., M.D., B.Ch., D.P.H. Camb., D.M.R. & E., Assistant Medical Officer in charge of the X ray department, St. Mary's Hospital.

Metropolitan Asylums Board: Borthwick, G. A., M.D., Ch.B. Edin., D.P.H., D.T.M. & H., and Rolleston, J. D., M.D., Ch.B. Oxf., Medical Superintendents in Infectious Hospital Service.

Manchester Royal Infirmary: Bramwell, J. C., M.D. Manch., M.R.C.P. Lond., an Honorary Assistant Physician; Tylecote, F. E., M.D. Manch., Physician.

Salford Royal Hospital: Addis, William Robert, M.B., Ch.B. Edin., Honorary Gynæcologist; Collins, Beatrice L., M.R.C.S., L.R.C.P., Radiologist.

# Vacancies.

*For further information refer to the advertisement columns.*

*Birmingham General Hospital.*—Asst. Surg. to Throat and Ear Dept. £50.

*Bradford, Grassington Sanatorium.*—Med. Supt. £700.

*Brighton, Royal Sussex County Hospital.*—H.S. £150. Also Hon. Dermatological Clin. Asst.

*Bristol Mental Hospital.*—Sen. Asst. M.O. £550.

*Cardiff City Mental Hospital, Whitchurch, near Cardiff.*—Res. Clin. Asst. for six months. 50 guineas.

*Cardiff, King Edward VII. Welsh National Memorial Association.*—Two Area Tuberculosis P.'s. Each £696.

*Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.*—Sen. and Jun. H.S. At rate of £100 and £50 respectively.

*Chelsea Hospital for Women, Arthur-street, Fulham-road, S.W.*—Anæsthetist. £21.

*City of London Maternity Hospital, City-road, E.C.*—Asst. Res. M.O. At rate of £80.

*Denbigh, North Wales Sanatorium, Llangwyfan, near Denbigh.*—Third Asst. Res. M.O. £200.

*Dewsbury County Borough.*—Asst. Sch. M.O. and Asst. M.O.H. £600.

*Dreadnought Hospital, Greenwich, S.E.*—H.S. and H.P. Each at rate of £110.

*Elizabeth Garrett Anderson Hospital, 144, Euston-road, N.W.*—Asst. Med. O. Ven. Dis. Dept. £1 1s. per attendance. two Anæsthetists. At rate of £10 10s.

*Evelina Hospital for Children, Southwark, S.E.*—H.S. At rate of £120.

*Folkestone, Royal Victoria Hospital.*—Res. M.O. At rate of £150.

*Fulham School Medical Treatment Centre.*—Ophth. S. £50 per quarter.

*Halifax Royal Infirmary.*—Third H.S. At rate of £150.

*Hampstead Borough.*—Four Consulting Obstetricians.

*Hartlepool Borough.*—M.O.H., &c. £800.

*Herts County Mental Hospital, Hill End, St. Albans.*—Sen. Asst. M.O. £600.

*Hospital for Sick Children, Great Ormond-street, W.C.*—H.S., H.P., and Asst. Cas. O. £50 in each case.

*St. Thomas's Hospital.*—P.

*Southampton County Borough.*—Tuberculosis O. £750.

*South London Hospital for Women, South Side, Clapham Common, S.W.*—H.P. and three H.S.'s. All at rate of £50.

*West London Hospital, Hammersmith-road, W.*—Hon. Med. Radiologist.

*Willesden Urban District Council.*—Consulting Ophth. S. 4 guineas per session.

# Births, Marriages, and Deaths.

## BIRTHS.

Darbyshire.—On Feb. 24th, to Dr. Florence Darbyshire, wife of Dr. F. J. Darbyshire, Westbourne Park-road, W.—a son.

Harries.—On the 7th inst., at a nursing home, the wife of Eric H. R. Harries, M.D. Lond., City Hospital, Little Bromwich, Birmingham—a daughter.

Holmes.—On March 2nd, at Tower House, Burgess Hill, Sussex, the wife of Lieut.-Colonel J. M. Holmes, I.M.S. (retd.), of a daughter.

Howarth.—On March 6th, at Devonshire-place, W., the wife of Walter Howarth, F.R.C.S., of a son.

Jacques.—On Feb. 27th, at a nursing home, Clifton, Bristol, to Evelyn Jacques, wife of Frederic Jacques (both of the Malayan Medical Service)—twin daughters.

McFadyean.—On March 6th, at Herne-hill, S.E., the wife of Kenneth McFadyean, M.R.C.S., L.R.C.P., of a son.

## MARRIAGES.

Kilner—Brennan.—On Feb. 23rd, at St. James's Church, Spanish-place, T. Pomfret Kilner, F.R.C.S., to Florence, widow of Lieut. J. Brennan, Lancs Hussars.

Wigram—Woolfe.—On Feb. 22nd, at the St. John's Wood Synagogue, N. G. Wigram, F.R.C.S., to Dorothy, second daughter of Mr. and Mrs. John Woolfe, of Finchley-road, London.

## DEATHS.

Leigh Cox.—On Feb. 28th, at a Boscombe nursing home, Wilfred Leigh Cox, M.R.C.S., L.R.C.P., of Beresford-road, West Southbourne.

Sullivan.—On Feb. 26th, at Bournemouth, Dr. W. C. Sullivan, Medical Superintendent, Broadmoor Criminal Lunatic Asylum, aged 57 years.

Surrage.—On March 7th, at King's College Hospital, Harold James Rocke Surrage, M.R.C.S., L.R.C.P., of George-street, Portman-square, in his 32nd year.

Yelf.—On Feb. 28th, at Hemel Hempstead, John Burnet Yelf, M.R.C.S., L.R.C.P. (late of Shipston-on-Stour).

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Comments, and Abstracts.

## CHILD WELFARE: REVIEW OF A YEAR'S WORK

The annual meeting of the National Baby Week Council was held at Carnegie House, Piccadilly, on March 4th, under the presidency of Dr. Mary Scharlieb She referred to the still high mortality of infants in the first four weeks of life, to combat which well-qualified doctors, nurses, and midwives were necessary. The Astor challenge shield for the most effective baby week campaign was won by Northampton, and Astor banners by Littlehampton and Arundel and by Wigan, while certificates of merit went to Blackburn, Middleton, East and West Molesey, Rathmines (Dublin), Walsall, and Walthamstow. These were presented by Dr. Scharlieb during the afternoon.

Dr. Eric Pritchard moved the adoption of the annual report. The year's work showed three new features—Baby Sunday, with a mass meeting in the Queen's Hall, the Empire's mother and baby competition; and the first summer school of maternity and child welfare. The motion was seconded by Dr. David Kirkhope and carried, as was the report of the joint honorary treasurers and the balance-sheet introduced by Major C P. Lovelock.

An address on the Economics of Child Welfare Work was then given by Dr. J R. Kaye, M O.H. of the West Riding. There were, he said, two aspects of health services—the positive, dealing with the promotion of health, and the negative, concerned with mortality and morbidity Prevention or restriction of disease was one of the best ways of promoting health, and of all factors leading to it maternity and child welfare work was perhaps the most fruitful, though the most modern. While we spent every year £1,750,000 on asylums, £750,000 on mental deficiency, and £3,000,000 on tuberculosis, we only spent £1,500,000 on maternity and child welfare, which was preventive work. Welfare centres were not repair shops or surgeries; we wanted them to be attended by well babies and good mothers. The work of health visitors in the homes was of great service in maintaining health. There were 105 centres in the West Riding, and Dr. Kaye reckoned that a centre could be established for £100 and carried on at a cost of £100 year

The Hon. Mrs. Bernard James then spoke on the Rural Child. People thought of country children as being specially fortunate in the matter of healthy environment, but there was another side to the question. Shortage of houses often meant that two families had to share a cottage, and this created a terrible problem in cases of illness, especially if it was infectious illness. The water-supply was frequently dependent on a well, a pump, or a rain-water tank, and the water might be dirty or contaminated. Many houses had no proper sanitation, and the arrangements were, in some cases, neither clean nor healthy. There were difficulties arising from poverty; the agricultural worker's wage was slight fit when everybody was well, and it was hard that, if one child needed a little extra, all the others had to go short There was often no hospital near at hand, and many places had no district nurse, while a doctor was an expensive luxury only resorted to in cases of serious illness The result was that mothers had no systematic help in regard to their children's health. A good district nurse and midwife was invaluable; most of the 70 district nurses in Buckinghamshire acted also as school nurses and health visitors, and became the trusted friends of the families. There were advantages in having medical officers of the centres from a distance, and it was desirable to have doctors, preferably women, who had specialised in children's work. The right thing was to establish centres in the central villages and send an omnibus to fetch mothers and children from the surrounding districts. This was done in Mrs. James's own district, and the Ministry of Health, after sending down an inspector, had allowed their claim for grant in respect of conveyances.

## THE PREVALENCE OF CANCER.

A lay correspondent complains that he is confused by reason of statements in the press in regard to medical matters, and asks how he can learn the truth. "On one day," he says, "I am told that cancer is on the increase, and on another that it is no more prevalent now than it was 100 years ago," and he encloses the extracts from the newspapers. We sympathise with our correspondent, who suffers in common with many others, but can only refer him to the official figures of the Registrar-General. Newspaper readers desire sensational statements, and do not fully realise the evil which is done by them. In the matter of cancer, misleading pronouncements may be particularly serious, especially when some method of therapeutics is vaunted. For a sense of false security may be engendered which obstructs that early treatment which is at present the only safeguard. The newspaper extracts which contradicted each other managed to be both wrong.

## A HOSPITAL IN CHINA.

Before his departure from China recently, Dr. R. R. Walker was present at the opening of a new maternity building attached to the Church Missionary Society's hospital at Hinghua (Fukien), with which he has been connected for 18 years. This building was a gift from the people of the city, who had subscribed 50,000 dollars in token of appreciation of the services of Dr and Mrs Walker. The Hinghua hospital was founded 30 years ago by the C.M.S., and was for 17 years under the charge of Dr. van Someren Taylor It has 380 beds, besides 60 beds in the new maternity building, and for a long time Dr. Walker has been the only British doctor there. He has been assisted, however, by five Chinese doctors, three English sisters, 20 Chinese women nurses, and four Chinese men nurses. During the past few years wounded soldiers and bandits have formed a large proportion of his patients, and on several occasions he has been asked by the Governor of the city to act as mediator between opposing forces in the perpetual civil war.

## *OPEN AIR SHELTERS.*

The open-air shelters manufactured by the Papworth Industries, Cambridge, all of which are of good material, are now being sold at prices ranging between £12 and £20. Particularly worthy of notice is the "Country" shelter, which can be made with the roof and front jointed so as to allow the whole structure to be passed through a six foot doorway, an advantage where there is no side entrance to the garden of a house. The revolving shelter, which turns at a touch, is also a portable building which has decided merits.

Our readers will like to know where useful adjuncts to what is often protracted treatment can be obtained in a form that is available promptly without much expenditure.

## THE LORDSHIP OF THE WORLD.

We have received this small book dealing with the large subject of the inter relations of the British Empire, the United States, and Germany (C. J O'Donnell. London: Cecil Palmer Pp 187 5s.) and find it to be an uncompromising piece of political writing which contains no particular appeal to the medical profession Many popular views are contravened and much vigorous phraseology is employed in general deductions, which will not always be held justified by the facts, even if it is admitted that the facts are so, or are set out in due proportion. None the less, it is a book which will appeal to a certain mode of thought among medical men, if only because of the many illustrations that are provided in it of the sinister influence of common conceptions, when not founded upon reason. Medical men, whose business it is to be familiar with the mental make-up of their fellows, know perfectly well that the various proceedings and policies denounced whole-heartedly by Mr. O'Donnell did not have their origin in cruelty or malice, but publicists insist so strongly upon the essential malignancy of those to whom they are opposed that readers who do not think acquire passively many contorted views of the world No doubt there is much in what Mr. O'Donnell has written that we all ought to think about, but it would be unwise to adopt his outlook without probing his facts, or to endorse his conclusions without inquiry into their logical basis.

## AN AID TO THE STUDY OF MIDWIFERY.

Miss Olive Haydon, a member of the Central Midwives Board, has written a short guide[1] to those specimens in the museum of the Royal College of Surgeons of England which are likely to interest and instruct students of midwifery. It is intended primarily for midwives, but if it encourages medical students to make more use of the admirable material on view in the museum it will be doing a service to them also. It is undoubtedly convenient to carry such a guide on a visit—or preferably on several visits—to the museum, and there is no doubt that anyone who examines the exhibits to which it refers will afterwards find it much easier to take in the mass of facts which the student is asked to learn within a few months. We doubt whether all medical students understand that the museum is open to them. Those who never go to the College except under the stress of examination are certainly unwise, for some of the collections are admirably adapted to the student's needs and are beautifully arranged.

## A CONVALESCENT HOME FOR THE MIDDLE-CLASSES.

A CONVALESCENT home has been opened at the New Hall, Dovercourt, to cater for those who cannot afford the large fees asked in nursing homes, and do not care to go to those supported by charity. *It is open to all employees of any* place of business, banks, works, or to the "new poor." The home, situated in its own grounds, overlooks the sea, and is designed to be not an institution but a pleasant home, where everything is done for the comfort of the patient. The rooms are large and airy, and books, papers, and games are supplied. The staff is adequate, and the home is visited by Dr. Ford Porter, medical officer of health of the district. The price charged is 30*s.* per week inclusive. Applications for admission should be made to the London office to Captain Claremont, R.N., 52, Abingdon-villas, Kensington, W. 8.

We bring the home before our readers with the belief that many of them will know patients who might be greatly benefited by the opportunities offered. It need hardly be said that the extraordinary moderation of the fee is due to the fact that the whole service and administration are supplied gratuitously by Captain Claremont and his wife and assistants.

## ERYTHEMA NODOSUM AND TUBERCULOSIS

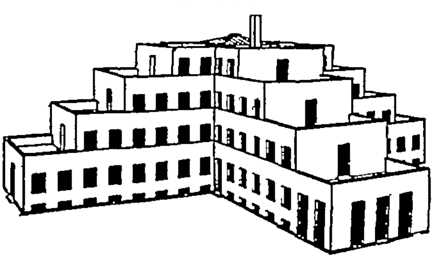
IN the *Semana Medica* (Buenos Aires) of Jan. 7th Prof. G. Alforo summarises his 30 years' experience of erythema nodosum. His conclusions are as follows: (1) Erythema nodosum may be the expression of various infections but not of any one in particular. (2) Nevertheless, the almost constant coincidence of positive tuberculin reaction and the presence of Koch's bacilli in some nodules, shown by staining or inoculation, prove that it is usually a manifestation of tuberculosis. (3) Not infrequently the general symptoms (loss of appetite, weakness, and fever) which precede and go with the eruption suggest a larval or attenuated tuberculosis. (4) In some cases observed by Prof. Alforo erythema nodosum has shown itself as the final episode in a febrile attack lasting some weeks, and has cut short a budding tuberculosis in children with a positive tuberculin reaction and enlargement of the tracheo-bronchial glands. In such cases, he states, it seems to be an exanthem of fixation of the tuberculous virus and to determine favourably a miliary infection probably attenuated.

## TERRACED BUILDINGS.

THE drawings reproduced represent an ingenious type of building devised by Mr. Gjerlov-Knudsen, an architect of Copenhagen. The artistic merits of the design may not alone be sufficient to commend it, but there are certain very obvious advantages in this kind of city dwelling which make it worth consideration.

The figures show a block of flats in perspective and in cross-section. The building is in the form of a cross, and it is built in terraces. Each arm of the cross is arranged to form a complete dwelling or flat, and it will be clear from the pictures that the size of the wings or flats diminishes towards the apex of the pyramid, until at the top they become very small indeed. In the centre of the cross there is a communal staircase or lift, and presumably the occupants of the apartments arrange themselves in layers according to financial status. In the building specified there are five rooms, together with a small room and a bathroom, in the first-floor flats; three rooms with a small room and a bathroom in the second-floor flats; and two rooms and a shower bath in the third-floor flats. Each kitchen is connected with the basement through a special shaft with a transport lift. Refuse may be transported through this in special baskets. There are isolated rooms in the basement for dustbins, and also the necessary rooms for washing and drying, besides store-rooms, bicycle-rooms, and a lumber-room for each apartment. "The plans especially intended for England are furnished with fireplaces meant for gas, and, in some cases, coal fires."

FIG. 1.



A block of flats in perspective.

It is easy to see the advantages of the plan. Every room in every flat can have large windows looking out on an open space; every occupant can have plenty of fresh air and light. Each flat, moreover, possesses a small terrace of its own which can be used by children for their play or can be turned into a miniature garden. Where several of these buildings are built close to one another, none of them will take the light from the windows or terraces of any other, and the streets will not be darkened as they are by perpendicular houses. In a detailed communication Mr. Gjerlov-Knudsen has shown how he would adapt his building to the needs of a sanatorium, convalescent home, or seaside hotel, and it seems particularly fitted for such purposes.

The amenities are obvious; but it is equally clear that construction would be expensive. First of all, the site would have to be bigger than that of the ordinary block building, because so much space is "wasted" by the cruciform plan. Owing to the limited accommodation in the upper storeys there would be a smaller number of tenants to pay rent than might be expected in a building covering so much ground. The vast area of the outside walls would be very far from economical, and there is the added objection that the *inside* walls in the lower storeys would have to be strongly constructed so as to bear the weight of the distal outside walls of the flats above them. At the present time it is largely lack of money that prevents the construction of more and better houses, and architects already do what they can to bring light and air into their buildings. But where money can be spared, or where a wealthy client can be induced to sacrifice external decoration to the health of those who have to live in his building, there is certainly scope for the application of the Danish plan in its essentials. Light and air are worth great sacrifices. In the meantime it will be reserved for some nation looking at other than pecuniary results to build the first complete town of terrace buildings, for which Mr. Gjerlov-Knudsen has already devised an alarmingly symmetrical plan. Further particulars can be had from him at Dosseringen, 36, Copenhagen.

## A BOOK ABOUT SUGAR.

AN interesting little book[1] by Mr. Geoffrey Fairrie, designed to present general information about sugar in such a form that it can be easily understood by the man-in-the-street, has reached us. The volume is not, however, solely for popular consumption, since it contains a considerable amount of up-to-date technical detail which should be of considerable value to the serious student. Although the author is a director of the largest privately-owned sugar refinery in the world, the point of view presented is not exclusively that of the refiner; he deals impartially with every aspect of the subject, without so much as hinting as to whether the establishment of the beet sugar industry in this country is likely to affect the refining industry adversely or not. The book opens with a brief chapter on "How the plant makes sugar"; then follow two chapters on the outlines of the production of raw cane and beet sugars respectively. In the fourth chapter the production of unrefined direct consumption sugars are described, and the two following chapters are devoted to modern refining processes; the second of these chapters contains a valuable section on charcoal and decolourising carbons, in which will be found a considerable amount of first-hand information which is not otherwise so easily accessible. The seventh chapter is historical, being devoted to old-time methods and their development; chapter eight contains a brief and popular account of the physiological aspects of carbohydrate metabolism, and in the ninth chapter are described a number of other sweetening agents, such as maple sugar, glucose, lævulose, syrups, and molasses.

Although the number of works dealing with the manufacture of sugar is considerable, we know of no book which gives such a comprehensive account of the whole subject of sugar, and we can recommend it as a readable book containing reliable information.

# Goulstonian Lectures

ON THE

# DEVELOPMENT OF PSYCHO-PATHOLOGY

## AND ITS PLACE IN MEDICINE.

*elivered at the Royal College of Physicians of London on March 11th, 16th, and 18th, 1926,*

BY BERNARD HART, M.D., F.R.C.P. LOND.,
PHYSICIAN IN PSYCHOLOGICAL MEDICINE, UNIVERSITY COLLEGE HOSPITAL.

## LECTURE I.

DURING the past few decades psychology has merged with disconcerting vigour from the paths of cademic quietude, and has laid claim to a substantial hare in the practical affairs of mankind. It has serted its right to a place in the proud structure f the sciences, and its right to contribute to the nderstanding and control of the actual problems of uman life. Among those problems is the causation nd treatment of disease, and it is to the endeavours nd achievements of psychology in this sphere that the present lectures are devoted. Our task will be to race out the development of the psychological pproach in medicine, to consider the scientific and medical value of the successive stages in that development, and finally to estimate the place in medicine to which the psychopathology of to-day is entitled.

The justification of such a survey hardly requires demonstration. Interest in morbid psychology has ncreased in a remarkable manner during this century, and at the present time there is a veritable spate of literature dealing with the subject. It is true that much of this has but little value from the standpoint of science, but some of it is solid work, and the claim is made that psychopathology has succeeded in elucidating, at any rate in large measure, the problem of the nature and causation of the psychoneuroses. Such a claim, relating as it does to a group of disorders which form a not inconsiderable portion of medical practice, clearly merits careful examination and appraisement.

Our task, then, is to describe the history of psychopathology as a branch of medicine, to evaluate its achievements, and to consider how far it has succeeded in establishing a secure position within the fold of science. As a preliminary measure it will be helpful to define the precise meaning of some of the terms in this statement of our aim, so that the extent and limitations of the path we desire to traverse may be clearly marked out.

### DEFINITION OF PSYCHOPATHOLOGY.

"Psychopathology" connotes, not a mere description of mental symptoms, but *an endeavour to explain* disorder or certain disorders in terms of psychological processes. The distinction expressed here is of the greatest importance for a clear understanding of the subject. The description of mental symptoms constitutes clinical psychiatry, and is as distinct from psychopathology as clinical medicine is from pathology. In the former case we are concerned with the recording of clinical phenomena, in the latter with the elucidation of the processes responsible for those phenomena. To enumerate the delusions which a patient expresses is not psychopathology but clinical psychiatry, and we do not pass beyond this until we endeavour to explain the incidence of the delusions in terms of causal processes. Moreover, this explanation is only psychopathological if it is couched in the language of psychology and built up of psychological conceptions. Drever has remarked that "the indirect explanation of experience in terms of nervous structure and nervous process is no psychological explanation at all, but a physiological one,"[1] and it is equally true that the explanation of morbid mental symptoms in terms of brain may be excellent pathology, but it is not psychopathology. How far it is possible and useful to explain disorder by means of psychological conceptions, or, in other words, how far psychopathology deserves a place in scientific medicine, is, of course, a legitimate question, and one which forms a chief subject of inquiry in these lectures; but we cannot even begin to answer it unless it is clearly understood that psychopathology does not mean a physiological explanation of mental disorder, but a psychological explanation of disorder, whether that disorder is mental or physical in its manifestations. For example, an explanation of the intellectual enfeeblement of senile dementia in terms of the lesions found in the brain is a physiological interpretation, although the phenomena explained are mental in character, while an explanation of hysterical paralysis in terms of suggestion is psychopathological although the phenomena explained are physical in character.

In the light of these considerations it will be understood that in the present lectures we are only indirectly concerned with clinical psychiatry, and that its history and development do not enter into our inquiry. It is noteworthy, indeed, that psychopathology has mainly grown, not from the study of insanity, but from the investigation of hysteria, in which the phenomena are in great part physical in their manifestations.

In the definition of psychopathology which has been given above, the word "explain" is used in the sense in which it constitutes the goal of scientific method. Karl Pearson, in his classical "Grammar of Science,"[2] has analysed the fundamental features which distinguish science from all other attempts to deal with our experience, and the principles which he enunciates will serve as a standard whereby the claims of psychopathology can be tested and appraised. The essential character of science resides, not in the nature of the facts with which it deals, but in the method of attack which it employs. This method consists in three successive steps. Firstly, the observation of phenomena; secondly, the orderly arrangement and classification of the facts which have been observed; and thirdly, the finding of "laws" which will serve to explain those facts and enable us to predict and control the occurrence of future phenomena of the same order. A body of knowledge which has traversed only the first two steps has attained to the level of a descriptive science, but it is imperfect and inadequate until it has succeeded in passing on to the third step. This third step involves a transition from phenomena to concepts. The "laws" which it formulates are not phenomena which can be observed in nature, but are constructed by the human mind in order to account for those phenomena. They are, in other words, conceptual abstractions whose sole claim to validity is that they do explain the observed facts. The history of our knowledge of planetary motion evolved from the observation of the successive positions occupied by the planets, through the classification of those positions by Kepler whereby it became apparent that the planets moved in ellipses round the sun, to the construction of the law of gravity by Newton which explained in a single and comprehensive formula the track and relations of the planetary movements. It is to be noted that the "laws" whose development constitutes the third step of science are not only conceptual in character, but are frequently built up of imagined entities which cannot possibly be observed, and may even involve qualities contradicting our general experience. For example, the phenomena of light are explained by the assumption of a weightless and frictionless ether, which not only cannot be observed but is imagined to possess qualities differing from those shown by every substance which has been observed. This freedom from the trammels of phenomenal reality which scientific conceptions claim to exercise will be found to be a point of fundamental importance when we have to consider the justification of such psychopathological concepts as the "unconscious." It is necessary to remark that this freedom is only relative. Science does not entitle us to construct conceptions built entirely in the air, but only such as conform to the rigid procedure of its method. That is to say, they must explain the observed facts, they must not be contradicted by other facts, and they must be capable of verification by repeated reference to experience and experiment. The theory of light, for example, assumes an ether and the movement of its particles according to the laws of wave motion, but it only has scientific validity because every time we test our calculations by reference to experience and experiment we find that the phenomena observed are precisely what the theory would anticipate them to be. In other words, the validity of a scientific conception is measured by the service it is able to perform in the understanding, the prediction, and the control of the facts of our experience. So long as it can do these things it has a place in science, but when the advance of our knowledge shows it to be inadequate in these respects or capable of being replaced by some wider and more satisfying conception it is to be ruthlessly scrapped.

### PSYCHOLOGICAL FACTORS IN ANCIENT AND PRIMITIVE MEDICINE.

This digression to the basic principles of science has been necessary in order that we may have at our disposal a definite standard whereby to assess the history and achievement of psychopathology, and with this in our possession we may now pass on to the proper subject of our inquiry. The first task to be attempted will be a summary review of the history of medicine with the object of discovering the beginnings of psychopathology, and the observations and conceptions which have served as the chief stones in its building. It may be said at once that psychopathology is a science of comparatively recent growth, and that hardly any traces of it are to be found before the middle of the nineteenth century. This may seem a strange statement in view of the prominent part played by apparently psychological procedures in medicine from the very dawn of history, and the oft-repeated assertion that psychotherapy is the oldest form of medical treatment. Nevertheless, a perusal of the facts in the light of the general principles already laid down will show that it is substantially true, and that to regard the views and practices of early medicine as the first stages in the development of psychopathology is historically and logically false.

If we look back to ancient medicine we find everywhere the same essential picture, disease regarded as the work of demons or of magic, and a corresponding treatment by the aid of incantations, charms, and exorcisms. Side by side with these demonological conceptions and therapies, however, there existed a certain number of simple surgical practices, and a herbal lore in which, amongst masses of extraordinary and revolting ingredients, one finds the names of drugs of undoubted efficacy and value. The Ebers papyrus (1550 B.C.),[3] for example, describes the incantations used in Egyptian medicine, but it also contains a list of remedies including such familiar drugs as opium, hyoscyamus, squills, and castor oil. The records of Babylonian medicine show a similar demonological view of the causation of disease, and detail the litanies and incantations necessary for its treatment. Diagnosis is closely connected with astrology, and is made by the interpretation of omens. "In the Old Testament disease is an expression of the wrath of God, to be removed only by moral reform, prayers, and sacrifice."[4] Yet in both these cases there is ample evidence of the use of simple surgical, herbal, and hygienic measures, apparently without relation to the supernatural conceptions applied to disease in general. It is, perhaps, legitimate to assume that the former originally developed on a basis of empirical observation essentially identical with that on which the structure of science was ultimately to be erected.

Primitive tribes existing at the present day show in their medical practice features closely comparable to those found everywhere in the medicine of antiquity. Disease is ascribed to the action of supernatural agents or of human magic, and treatment is carried out mainly by incantation, ceremonials, and exorcisms, but again we find a number of remedial practices, apparently divorced from the demonological theory and therapy, and including the use of drugs and such simple measures as poulticing and blood-letting.

There is definite evidence that in these primitive tribes demonological procedures are actually efficacious, and that by their aid disease may, in fact, be caused and cured. Rivers remarks, "There can be no question that such processes as I have recorded here are efficacious. Men who have offended one whom they believe to have magical powers sicken, and even die, as the direct result of their belief; and if the process has not gone too far, they will recover if they can be convinced that its spell has been removed. Similarly, one who has intruded on the haunt of a ghost or spirit will suffer, it may be, fatal illness, because he believes that he has lost his soul; and he will recover after the performance of rites to which he ascribes the power of restoring the lost soul to his body."[5] Now, it is true that in the light of modern knowledge such results as these can only be explained by the invocation of suggestion or some similar psychological process. But, as Rivers later says, "It is necessary . . . . to distinguish the production and treatment of disease by agencies acting through the mind from the knowledge that the measures used acted in this manner. Though remedies acting through the mind were probably the earliest to be employed by Man, the knowledge that the remedies act in this way is one of the most recent acquirements of medicine."[6] In other words, the remedies were not given as a result of the application of a psychological conception, but either on account of their supposed physical effect or in accordance with a magico-religious conception. It is probable that many of the successful results achieved by drugs at the present day owe that success to factors of a psychological order, but their use has nothing to do with psychopathology, although the latter may ultimately seek to utilise the results as facts of observation. Psychopathology is a body of knowledge, and it does not begin to exist until an attempt is made to explain the phenomena of disease in terms of psychological processes and by the aid of psychological conceptions. Practically no trace of such an attempt can be found in ancient or primitive medicine. It is to be noted, moreover, that in early medicine demonological conceptions and procedures were applied to all forms of disease indiscriminately, and not merely to those conditions which we now class as the psychoneuroses and psychoses.

The demonological methods of ancient medicine, therefore, form no part of the foundations from which psychopathology has arisen, although the results they achieved can now be best explained by psychological conceptions. The roots of psychopathology must be sought for elsewhere, and they are to be found in the soil from which all scientific medicine has grown. The search for these roots will be facilitated by taking as a basis Rivers's statement that the beliefs of mankind concerning the causation of disease fall into three categories: (*a*) human agency (magic), (*b*) supernatural agency, (*c*) natural causes.[7] In primitive medicine, ætiology and therapy are built almost exclusively on the first two—i.e., on magical and religious conceptions respectively. The category of natural causes hardly exists, but traces of it are, nevertheless, to be found in the domestic remedies and herbal lore which seem to have been employed everywhere side by side with the magical and religious practices.

It is this third category which contains science, although the latter is by no means co-extensive with a mere belief in the efficacy of natural causes. We shall see that it is possible to hold many beliefs about

---

[3] Garrison: An Introduction to the History of Medicine, third edition, 1921, p. 49. I am heavily indebted to this invaluable work for a considerable number of the historical details contained in these lectures.

[6] Rivers: Op. cit., p. 122.

[7] Rivers: Op. cit., p. 7.

"natural causes" which are certainly not cast in a scientific mould. Only with the gradual evolution of its peculiar method of attack did science succeed in building up a sharply defined body of knowledge within the general notion that disease was produced by natural causes rather than by magical or religious agencies. Now, psychology and psychopathology are, or claim to be, branches of science, and therefore their development was only possible from the third category, and not at all from the other two. The failure to appreciate this necessary axiom was the cause of the long retardation of psychology in the advance of the sciences, and its trammelling with religion and ethics.

The magical and religious categories of primitive medicine frequently crop up throughout later history, dominating the picture in the Middle Ages, and occurring sporadically even in modern times; for example, in Heinroth's doctrine that mental disorder is due to sin and in the present-day conceptions of Christian Science. But they lie altogether outside the path of development of scientific medicine, and our only interest here is in the gradual evolution of the category of natural causes.

### ORIGINS OF SCIENTIFIC MEDICINE.

In Greek medicine we note the beginnings of what may be termed a philosophical approach to the problems of medicine. Empedocles (504–443 B.C.) introduced the doctrine of four elements (earth, air, fire, and water) as the four-fold root of all things, and conceived health as the result of their balance, and disease of their imbalance, in the human body. Later Greek writers postulated various other elements and qualities from whose combinations and permutations disorder could ensue, leading up to the "humoral pathology" embraced by Hippocrates, with its four essential humors, blood, phlegm, yellow bile, and black bile.[8] In these theories of the Greeks we have an excellent example of a conception of disease which is certainly constructed within the category of natural causes, and is in no sense magical or religious, but which differs radically from the conceptions of science. It differs because it was not built up by the method of science. Scientific conceptions are imaginative constructions, but they must be erected on a solid basis of observed facts, and constantly tested by repeated descents from the plane of imaginative construction to that of experience and experiment. The Grecian theories are imaginative constructions built entirely in the air, and without any basis or control on the plane of observed facts. Fortunately at the same time a certain amount of empirical knowledge began to accumulate, the direct descendant of the herbal and other simple remedial measures of older times, but immensely assisted by the development of clinical observation with Hippocrates. We know now that it was from this empirical knowledge that the structure of scientific medicine was ultimately to arise, and not at all from the proud but futile philosophical theories.

It is not necessary for our present purpose to trace out in detail the later history of the rise of scientific medicine. After the temporary submerging of all progress in the scholasticism and deductive mental exercises of the Middle Ages, medicine again began slowly to move forward. By the seventeenth century empirical knowledge had largely increased, and theories were developing which bore some relation to facts of observation, and gradually became more and more consistent with the method of science. These theories were constructed, however, of physical, physiological, and chemical conceptions; there was as yet hardly a trace of the birth of any psychological conception, and any germs of it detectable were generally hopelessly entangled with magico-religious conceptions. Here and there, however, we may note the sporadic appearance of a genuine psychological point of view in such writings as those of Henri de Mondeville (1260–1320), who in his surgical treatise counsels his readers to "Keep up your patient's spirits by music of viols and ten-stringed psaltery, or by forged letters describing the death of his enemies, or by telling him that he has been elected to a bishopric, if a churchman"[9]—a piece of advice which is decidedly psychological if its ethical standard is questionable.

The actual historical line of development of the psychological conception in medicine has its roots, though hardly its logical ancestry, in the seventeenth century views and practices with regard to animal magnetism, and the personal power of healing. The ground for this statement is that, although none of these procedures were employed as the result of a psychological conception of disease or of therapy, and none of them form part of the actual building of psychopathology, yet they led to the observation of certain phenomena which were ultimately incorporated in the conception of suggestion, the conception which may be regarded as the foundation-stone of modern psychopathology.

### "MAGNETISM" AS A HEALING FORCE.

The notion that magnetism was a force capable of influencing the human body, and of being used for curative purposes, is found far back in the history of medicine, but it was in the seventeenth century that it became elaborated and systematised. In 1608 Rudolph Goclenius,[10] a follower of Paracelsus, wrote of the magnetic treatment of wounds. The general curative powers of magnetism were described by Athanasius Kircher in 1643,[11] and in 1679 William Maxwell[12] produced a comprehensive account of magnetic therapy in which he propounded the theory that all disease is due to the withdrawal of vital fluid from the organs and can be remedied by restoring the necessary magnetic force. The theory of animal magnetism was therefore actually in existence long before the time of Mesmer, although its origin is often erroneously ascribed to him.

The personal power of healing is also a doctrine of extreme antiquity, and records of its use may be traced throughout history right down to the present day. The power has generally been held to be the prerogative only of certain persons, particularly royalty, and the "Royal Touch" for the cure of disease was frequently employed by English and French sovereigns up to the reigns of Queen Anne in this country and of Charles X. in France.[13] In the seventeenth century the closely similar procedure of treatment by "stroking" was carried out by less exalted persons, and Valentine Greatrix or Greatrakes acquired fame by the great number of cures which he effected by this means. In a print in my possession he is represented as treating a boy by stroking the patient's head with his two hands and is described as "famous for curing several deseases and distempers by the stroak of his hand only." One can hardly contemplate this print and its legend without being reminded of the methods employed later for the production of hypnosis, and the place of such practices as a stage in the ultimate development of hypnotism and the conception of suggestion cannot be doubted.

In 1766 Mesmer produced his thesis "De planetarum influxu," dealing with the influence of the planets on the human body, an influence which he believed to be due to a universal magnetic fluid. The distribution of this fluid in the body, upon which depended health or disease, could be altered by the will of another person, and cures thereby effected. It will be observed that this theory is substantially identical with that which had been proposed by William Maxwell nearly a hundred years earlier. Mesmer attempted to put his ideas into practice in Vienna and various other towns, but it was not until his removal to Paris in 1778 that he began to achieve success. Here he opened a clinic in which he treated all kinds of disease by "animal magnetism," under conditions in which it is difficult to avoid suspecting a considerable admixture of charlatanism with the sincerity which we may reasonably attribute to him. The patients were seated round a tub, the "baquet," containing various chemicals and protruding iron rods which were applied to the portion of the body affected, the room was darkened, music was provided, and Mesmer appeared in a lilac robe, passing from one patient to another and touching them with his hands or with his wand.[14] Whatever we may think of Mesmer's methods there can be no doubt that results were produced, and during the following half century animal magnetism attained an immense vogue. Magnetic societies were founded in Paris and many other towns, several journals entirely devoted to the subject appeared, and a great number of books were published. Phenomena of this kind do not necessarily indicate that a movement has any solidity or value, as we have melancholy reason to know in our own time, but it must be remembered that many of the advocates and investigators of magnetism were men of undoubted ability, knowledge, and standing, and that these men were absolutely convinced that a discovery of the first importance had been made. The reason for this remarkable circumstance is that the observations upon which the magnetisers built their theories were actual facts, facts which could be repeated and tested indefinitely, and, moreover, facts which were new, or at any rate newly appreciated. The theories were no doubt fantastic, but the facts were sound, and it was upon these facts that the building of psychopathology ultimately began.

The facts observed by the magnetisers in the course of their investigations may be said to have included practically all those taken up or rediscovered by the hypnotists of a later age. Amongst these phenomena may be mentioned the production and removal at the will of the magnetiser, of anæsthesias, paralyses, hallucinations, and somnambulisms, and the carrying out of what are now termed post-hypnotic suggestions, that is to say, the performance at some prescribed later time of an action commanded by the magnetiser during the magnetic state. The chief concern of the magnetisers was with therapeutics, but it is interesting to note that, although Mesmer and some of his followers applied their methods to all forms of disease, subsequent workers soon recognised that magnetic phenomena and curative results were best induced in neuropathic subjects. This circumstance indicates the first narrowing down to the definite path which ultimately led to the psychogenic conception of certain disorders.

The observations of the magnetisers were undoubtedly genuine and accurate, but they explained them by a theory which was already old, and which was certainly inadequate, the assumption of a magnetic fluid which passed between the operator and the patient. Teste,[15] for example, explained suggested blindness for a particular object as due to the magnetic fluid being placed round the object in question and thereby rendering it invisible. Nevertheless, the beginnings of a psychological conception were already apparent in the writings of the magnetisers. Janet[16] has pointed out that many of them distinguished clearly between the peculiar state (état hypotaxique) induced in the patient, and the actual suggestions (phénomènes idéoplastiques) which could be realised in that state. The magnetic fluid was invoked by these writers solely to account for the former, the latter being explained in purely psychological terms. The distinction corresponds precisely to that existing between the hypnotic state on the one hand, and the phenomena of suggestion which can be observed while it is present on the other hand, and it must be confessed that we are still far from having achieved a satisfactory understanding of the hypnotic state itself. It should be noted, moreover, that the magnetic theory which sought to explain it is not intrinsically absurd; the conception of animal magnetism is not in itself more fantastic than the assumption of a weightless and frictionless ether to account for the phenomena of light. Nevertheless, it failed because it was not constructed according to the method of science, and because it was found to be incompatible with many of the facts subsequently provided by experience and experiment.

### BRAID AND HYPNOTISM.

Psychopathology has descended, not from the magnetic theory, but from a reconsideration of the phenomena observed during the magnetic state. The psychological explanation of these, already foreshadowed in the works of some of the earliest magnetisers, was made more precise by Bertrand in France and by Braid in this country, and with these writers the conception of suggestion may be said to have definitely arisen. Braid put forward several theories in the course of his career, veering round gradually from a conception of the facts of mesmerism which was entirely physiological to one which was essentially psychological. He showed that the anæsthesias, paralyses, and other phenomena which had been ascribed to the action of magnets, metals, and peculiar passes were due to none of these things, but merely to the suggestive effect of the ideas aroused in the patient's mind by the operator's words and gestures. He reached the conclusion that "hypnotism," a word first proposed by Braid as a substitute for the formerly employed "mesmerism," and the phenomena to be observed during the hypnotic state, were produced by suggestion and to be explained by purely psychological principles.

It is difficult to disentangle from the complicated medical history of the first half of the nineteenth century a decision as to whom the actual credit of priority in this conception should be given. There can be no question that many of the earlier French writers had foreshadowed it, and the claims of Braid have been disputed.[17] It is clear, at any rate, that with the publication of the latter's "Neurypnology" in 1843 the conception of suggestion had been definitely established. The formulation of this conception is the historical foundation-stone of psychopathology. From it the whole structure can be traced, including all the schools which at present hold the field. Many of these schools diverged early from the simple conception of suggestion along an independent road, which will be subsequently considered in detail. For the moment, however, our concern will be to describe the later history of the concept of suggestion itself, and to arrive at an estimate of its value and place in medicine.

The investigation of hypnotism languished after the time of Braid, and it played but little part in medicine until its resuscitation by the studies of Charcot and of Bernheim in the 'eighties of last century. The place of Charcot in this history provides a pathetic picture of the irony of fate. A neurologist and a man of science, with a keen appreciation of the necessity of exact clinical observation and the establishment of objective facts, he constructed, apparently by the very use of these accurate methods, a body of doctrine which was even more false than that of the magnetisers, and which subsequent research has almost totally demolished. As a result of a rigid investigation of the phenomena described by the old magnetisers, carried out by himself and by his pupils at the Salpêtrière, in particular Paul Richer, the author of a monumental work on "Grande Hystérie,"[18] it was concluded that hypnosis was a condition capable of being produced purely by physical means; that it comprised three distinct stages, lethargy, catalepsy, and somnambulism, each stage being initiated and terminated by definite physical procedures—e.g., catalepsy by forcing open the patient's eyes, somnambulism by rubbing the head; that magnets and metals had a specific action in causing and removing anæsthesias and other phenomena; and that hypnosis was only found in association with hysteria and was practically identical therewith. These conclusions were based on the repeated examination of a small number of patients, all hysterics, at the Salpêtrière. From the standpoint of our later knowledge they afford an instructive and remarkable example of the extent to which observations made with extreme care and accuracy can be misapprehended and vitiated by the adoption of too narrow an angle of approach We know now that the effective agents were not the magnets and the physical procedures, but the words of the operator and the expectations of the patient; that the three stages were only an artificial result of the drilling and training to which the patients had been subjected by constant exhibitions and demonstrations, and that the physical procedures which produced them could be replaced by a word or any other agent in whose efficacy the patient had implicit faith. It is true that Charcot was acquainted with the conception of suggestion, but it is clear that he had no adequate understanding of its extent and application, and this fundamental omission was responsible for the complete ruin of the structure so laboriously erected. We need hardly note that the work of the Salpêtrière school in the domain of hypnotism contributed but little to the building of psychopathology, although, as we shall see later, Charcot's investigation of hysteria played a much more important part.

### BERNHEIM AND SUGGESTION.

The work of Bernheim, on the other hand, is in the direct line of the history we are endeavouring to follow He owed his introduction to the study of hypnotism to Liébault, a practitioner who had for some years carried out hypnotic treatment in Nancy, but it may be said that essentially he repeated the observations of Braid and arrived at conclusions practically identical with those of the latter, although amplified and extended in certain important directions Bernheim's book,[19] published in 1884, marked the appearance of a school of thought radically opposed to that of the Salpêtrière, and one which finally led to the complete overthrow of Charcot's views. The chief tenets of this school, the Nancy school as it is generally termed, are that all the phenomena observed by the old magnetisers, by the hypnotists, and by the Salpêtrière investigators are the result of suggestion, and the hypnotic state only a condition of somnolence with increased suggestibility, itself produced entirely by suggestion. Hypnosis is not a pathological phenomenon only to be found in hysterics, but a state which can be developed in the vast majority of normal people. Moreover, suggestion is a universal factor in mental life, it can and does act in everyone every day, and it can produce results, including therapeutic effects, without the intervention of hypnosis. Bernheim's wide conception of the place of suggestion has been aptly summarised by Milne Bramwell. "In other words, everyone is suggestible, and if you take someone and suggest to him to become more suggestible, that is hypnotism! Thus, suggestion not only excites the phenomena of hypnosis, but also explains them."[20]

We shall find later that there is ample ground for criticising the immensely extended part ascribed to suggestion by Bernheim, but we may pause here to note the marked effects which his view has exerted upon the subsequent development of psychological medicine. It has been responsible for a greatly increased recognition of the incidence and power of psychogenic factors in medical practice. This has been accompanied by the first clear appreciation of the suggestive character of many of the procedures of primitive medicine, and an understanding of, at any rate, one of the factors whereby those procedures attained success. Moreover, this viewpoint has been extended to the therapeutic practices of modern medicine, and has called attention to the necessity of differentiating the possible suggestive effects of drugs and other measures from the specific action which is ascribed to them On the other hand, it has led to a superficial use of the word suggestion as the explanation of all things psychological, and to an unfortunate tendency in the uninstructed to identify the entire spheres of psychopathology and psychotherapy with suggestion.

After Bernheim the historical development of suggestion has travelled along two roads which, although obviously closely connected with one another, have to some extent proceeded independently, the therapeutic and the ætiological. That suggestive therapy should have marched along a road largely independent of ætiological investigation is, indeed, a remarkable fact, and one which silently points to the inadequacy of such progress, but it is nevertheless true. Correlated with it is the further circumstance that the later writings on suggestive and hypnotic therapy show but little advance beyond the standpoint reached by Bernheim. Methods have been rendered more precise, and there has been a general though vague recognition that the methods are mainly applicable in certain types of disorder only —namely, the psychoneuroses Some of the writers have, moreover, concerned themselves with the mechanism of suggestion, but the general tendency has been to adopt suggestion as a kind of universal drug for the relief of symptoms, with scant investigation and discrimination of the causal processes responsible for those symptoms

Bernheim's recognition of the fact that suggestion can be applied without hypnosis has produced a differentiation of methods into hypnotic and non-hypnotic, the latter comprising frank verbal suggestion in the waking state, and suggestion by what may be termed a "vehicle," that is to say, the deliberate use of electricity, drugs, or other measures, not for their specific effect, but as a means of introducing a suggestion into the patient's mind.

Throughout the history of suggestion the observation has frequently been made that results were sometimes apparently produced by ideas originating in the patient's mind and without the intervention of a second person, the term "auto-suggestion" being finally evolved to indicate a process of this kind. This observation has, in recent years, become the basis of a school of therapy which, under the leadership of Coué and with the aid of the more or less systematic expositions of Baudoin[21] and other followers, has at the present time achieved a great vogue. Beyond, however, some interesting fresh formulations of familiar facts, this school does not seem to have contributed anything essentially new to our former knowledge.

It may be remarked that the waves of popularity which have marked the progress of mental therapy are an instructive object-lesson. Animal magnetism rose to an immense vogue and fell, hypnotism has risen and declined at least twice, Couéism and auto-suggestion are at the apex of a wave to-day, and a closely allied surge may be seen in the astonishingly immense developments of Christian Science, New Thought, and other doctrines It may be concluded that all these movements derive their temporary vitality from the undoubted fact that they do produce results, and therefore include somewhere within them principles of actual objective validity. We may call these principles faith and suggestion, but in this wide sense such terms are little more than a cloak for our ignorance. Whatever these principles may be, it is clear that they are of vital concern to medicine, and it is the duty of medicine to dissect them out from their trappings and allot them a defined place in our therapeutic armoury.

The second road along which the conception of suggestion has travelled concerns its application as a weapon of explanation in the causation of disorder. It was early perceived that suggestions were not only capable of removing symptoms, but also of producing them. Charcot, in his investigation of hysteria, came to the conclusion that certain of its phenomena were directly due to "ideas," an observation which, as we shall see, had an immense importance in directing the later development of psychopathology. Subsequent writers have endeavoured to show that these "ideas" were dependent, both in their origin and effect, upon the action of suggestion. This notion reached its full development in Babinski,[21] for whom the whole clinical picture of hysteria was nothing but a manifestation of the results of suggestion. We may remark here that Babinski's view, though true enough as far as it goes, is so vague and superficial as to be of little service to our understanding of the complex problems of hysteria, but a more detailed examination of its validity must be postponed until we have considered the position of the conception of suggestion as a whole. Suggestion is the first definite psychological conception which has been contributed to medicine, and it is therefore of fundamental importance that its nature and value should be accurately appraised. This problem cannot be attacked, however, until some general principles have been laid down to serve as a standard and test, and for this purpose it will be necessary to diverge for a moment from our direct path.

## THE PLACE OF PSYCHOLOGICAL INTERPRETATIONS OF DISORDER IN MEDICINE.

At the commencement of this lecture psychopathology was defined as an explanation of disorder by psychological conceptions, and it was pointed out that such an explanation must be sharply distinguished on the one hand from clinical psychiatry, and on the other hand from an interpretation of mental disorder by physiological conceptions. The question was left over, however, as to whether the explanation of disorder by psychological conceptions which psychopathology attempts is either possible, justifiable, or capable of forming a part of scientific knowledge. This question must now be taken up because, until it is answered, we have no sure ground from which suggestion and the later contributions of psychopathology to medicine can be judged.

The problem at issue is essentially a part of the wider problem as to whether psychology and interpretations in psychological terms have a right and a place in science. This claim was for a long time disputed, the opposition reaching its culmination in the materialistic philosophy of the nineteenth century scientists, who held that psychology dealt with non-material and non-spatial processes which were "epiphenomenal" and "unreal," and therefore incapable of scientific treatment. Their view arose from two bases, the first being the unsatisfactory condition of the psychology of those days, for it was then an arm-chair production achieved by methods radically distinct from those which were proving so successful in the building of chemistry, physics, and other sciences; while the second base was a total misapprehension of the real nature of science. This misapprehension was cleared away by the work of Karl Pearson and other investigators who, as we have seen, showed that science is characterised, not by the nature of the facts with which it deals, but by the method of its attack, and that this method consists in the collection of facts, the classification of the facts collected, and finally the construction of conceptions which serve to explain those facts. Clearly there is nothing in this definition to exclude from the field of science mental as opposed to material facts, nor psychological as opposed to other conceptions. The sole criterion which science demands is that the facts must be rigidly observed, and the conceptions must be constructed according to the rules of scientific method. So soon as these simple principles were grasped it was obvious that psychology had a right to contribute its quota to the scientific understanding of life and behaviour.

The behaviour of living organisms has been attacked by several branches of science, each regarding the phenomena from its own standpoint, and interpreting them in terms of its own concepts. Biology, for example, interprets the phenomena in terms of life processes and biological laws, physiology in terms of nervous energy, reflex action, and so forth, chemistry in terms of the interaction of chemical compounds. The essential point which it is desired to emphasise is that there is not one science of living organisms, but a number of different methods of approach, each striving to deal with the phenomena by the aid of its own concepts, and measuring its success solely by the extent to which it achieves the explanation and the control of those phenomena. Psychology has established its claim to rank among these methods of approach, and to attempt an explanation of the phenomena by psychological conceptions, just as chemistry has a right to attempt an explanation by chemical conceptions. Each of these various and more or less independent methods of approach endeavours to attack as much of the field as it can, but it is found that while some of the phenomena are capable of explanation by the concepts of more than one branch of science, some can be more intelligibly and usefully explained by the concepts of one branch rather than by those of another, and some are at present capable of explanation by the concepts of one branch only. When the concepts of one branch are less comprehensive and widely applicable than those of another there is always a hope that the former will ultimately be reduced to the latter. For example, we may reasonably anticipate that the concepts of nervous energy and reflex action will ultimately be reduced to the concepts of chemistry and physics. But such a reduction is mostly a goal of the future, and for the present each branch must be content to explain whatever phenomena it can in terms of its own concepts.

Now all these privileges and limitations appertain to psychology in the same measure as they appertain to the other branches of science which are attacking the problems of living organisms. Equally with the latter, psychology must be allowed to formulate its own concepts, and the value and validity of these must be tested solely by their capacity to explain and predict the phenomena, or, in other words, by what can be done by their aid. Again, we may look forward to a time when it may be possible to reduce the conceptions of psychology to the wider concepts of physiology or the still wider concepts of chemistry and physics. But this desirable consummation is brought no nearer by the expedient of pretending it has been attained. There are many phenomena for which at the present time no other science than psychology can devise a feasible explanation, and many others in which psychological conceptions are more illuminating and helpful than physiological. We shall see that this statement applies to certain phenomena of disease, and so long as it holds we must gratefully accept what assistance psychology is able to offer us, provided the assistance is built up by a rigid application of the method of science. It is not that a psychological explanation is right and a physiological explanation wrong; it is merely that in certain spheres it is more profitable to employ a psychological than a physiological conception. Similarly, if we talk of a disorder as psychogenic it does not mean that no physiological, chemical, or physical explanation will ultimately be possible, but only that with our existing knowledge a psychological explanation is more useful. In other words, a psychological conception of a disorder may enable us to understand and treat our patients, and if it does so it is sound science and sound medicine, far sounder than the construction of a quasi-physiological hypothesis built altogether in the air, without relation to any observed facts, and with which it is possible to accomplish nothing. It would seem almost unnecessary to labour these simple and obvious facts, but the quaint notions of the Victorian philosophers concerning the reality of nervous energy and the futility of ideas are not entirely extinct even in the medicine of to-day.

## THE PLACE OF SUGGESTION IN MEDICINE.

Armed with these general principles we may now return from our digression into the philosophy of science, and take up again the consideration of the conception of suggestion. Clearly this conception is based on observed facts, and it enables us in some measure to explain and to control the facts. Therefore, so far as its form is concerned, it is validly constructed according to the method of science and, as it is entirely couched in psychological terms, it is entitled to a place in psychopathology. Its precise value, however, must be determined by a consideration of the facts which it claims to interpret, and its capacity to resume and explain those facts.

---

[21] Babinski et Froment: Hystérie-Pithiatisme et troubles nerveux d'ordre réflexe, 1917.

If we examine the phenomena for whose explanation suggestion has been invoked we find that these are extraordinarily numerous and diverse. When Bernheim was developing his theory that the facts of animal magnetism and hypnotism were attributable to suggestion, he made that conception so wide that Milne Bramwell was constrained to remark "In Bernheim's hands the word 'suggestion' has acquired an entirely new signification, and differs only in name from the 'odylic' force of the mesmerists. It has become mysterious and all-powerful and is supposed to be capable, not only of evoking and explaining all the phenomena of hypnotism, but also of originating—nay, even of being—the condition itself."[23] Since those days the limits have been pushed wider still; Babinski holds that suggestion is responsible for all the phenomena of hysteria, other writers use it to explain practically every symptom met with in the psychoneuroses. Others, again, maintain that all the methods of psychotherapy, however diverse they may apparently be, depend entirely for their effect upon the explicit or implicit use of suggestion. Finally, psychologists tell us that suggestion is a normal process in the human mind, and some believe that it explains our religious and political views, our caprices, and our prejudices. Now it is plain that a causal principle which is invoked for the interpretation of so many radically diverse phenomena must be a factor so widespread and universally active that it is a quite inadequate explanation of any particular phenomenon. We may suspect, indeed, that for many writers the word suggestion means little more than a vague recognition that a certain phenomenon is to be attributed to a psychological cause. Obviously, however, if suggestion is to be a concept of value in science or in medicine it must be brought within much narrower limits than these; and in recent years many attempts have been made to arrive at a definition marking off a limited and homogeneous group of mental processes. It cannot be said that any of these attempts has achieved an entirely satisfactory result, but we have at least attained a more precise knowledge of the various processes which have been at one time or another subsumed under the term suggestion. Among these processes are some—for example, the simple communication of an idea from one person to another—which are so general and elementary that they have no value as part of a limited concept. Another process, the influencing of thought and action by the existence of emotional systems which tend to inhibit ideas inimical to the goal of the emotional system and to enhance those in consonance therewith, is so universal that it does not take us far in the understanding of any particular phenomenon unless the precise nature and mode of action of the emotional system involved is stated. It is this process that is no doubt partly responsible for our politics, prejudices, and indeed for much of our mental activity. Suggestion, however it may be defined, is certainly to be regarded as one of its manifestations, but unless the term can be limited to a particular area of this very wide field it cannot have much value as a weapon of explanation. One possible limitation is to include in suggestion only the process whereby an idea[24] which has been communicated from one person to another undergoes a further development and realisation in the mind of the second person owing to the inhibition of all ideas which would normally counteract it, this development and inhibition being due to the existence of a peculiar affective relationship between the two persons. This sense would correspond to that in which the term is used to indicate a particular therapeutic procedure carried out by a physician upon his patient, and it would include a considerable number of the phenomena commonly attributed to suggestion in everyday life, but it would clearly not be applicable to any and every process generated by an emotional system. Another possible limitation is to indicate by suggestion only the process whereby an idea undergoes development and realisation owing to the inhibition of counteracting ideas. This is, of course, a much wider concept than the last because it does not specify that the force responsible for the inhibition arises from the affective relationship between two people, but permits of any force playing this part. It would therefore include auto-suggestion, and the mechanism which Babinski conceives to be responsible for hysterical symptoms, as well as a great number of other phenomena—in fact, practically all those which we have already characterised as the result of the working of an emotional system.

It is impossible here to enter into these complicated questions in detail,[25] but enough has been said to show that suggestion is by no means the exact and definite conception which it is sometimes thought to be, and that it is used by writers in senses which are materially different both in their connotation and denotation. Probably the central kernel of all these various usages is the development and realisation of an idea owing to the inhibition of counteracting ideas by some affective force. This is undoubtedly a process of great practical importance, and a single term to indicate it would obviously be convenient. Processes of this kind are so universal, however, that their recognition will only give us a superficial understanding of any individual phenomenon unless we are in a position to go further, and can specify the affective force concerned, and the precise mechanism whereby certain particular ideas are developed while others are inhibited. When Babinski tells us, for example, that the symptoms of a hysterical patient are to be explained by suggestion, the statement is true enough if suggestion is taken in the general sense which we have described, but it leaves out almost everything worth explaining: why this particular patient is so abnormally suggestible, what is the particular emotional force responsible for the suggestion, and why he has developed just these symptoms and not others.

We may conclude, therefore, that suggestion is a legitimate psychopathological conception, provided that it is used in one or other of the defined and limited senses indicated, but that it only takes us one step towards the solving of the problems we have to meet. This one step, indeed, is of supreme importance, because it carries with it the recognition of the psychogenic origin of certain disorders, and implies all the significant changes in medical theory and practice which must inevitably follow from that recognition. Nevertheless, to regard suggestion as a completely satisfying explanation of the clinical picture presented by an individual patient would be as futile as to regard the electric current proceeding from a water-driven dynamo as completely explained by the law of gravity. It is owing to this superficial character of the conception they employ that the later history of the suggestionist schools has been comparatively sterile. They have developed some useful practical methods, but in the understanding of patients and their illnesses they have progressed but little beyond the standpoint of the early hypnotists, or indeed, of the early magnetisers. For this understanding we must turn to schools whose conceptions are more detailed and precise than that of suggestion.

---

[23] Milne Bramwell: Op. cit., p. 337.

[24] The term "idea" has been deliberately employed in this passage because of its conveniently elastic significance, though it may be objected that it savours of an old and exploded psychological theory.

[25] See Bernard Hart: The Methods of Psychotherapy, Proc. Roy. Soc. of Medicine, 1918. A valuable review of the whole problem will be found in Dr. Ernest Jones's paper, The Nature of Auto-Suggestion, Brit. Jour. of Med. Psychol., 1923.

# EARLY PUERPERAL RETROVERSION.

By VICTOR LACK, M.B., B.S., M.R.C.P. Lond., F.R.C.S. Edin.,
ASSISTANT OBSTETRIC AND GYNÆCOLOGICAL SURGEON, LONDON HOSPITAL; LATE LECTURER IN MIDWIFERY TO THE UNIVERSITY OF BIRMINGHAM.

Retroversion of the uterus may give rise to a variety of symptoms. Unfortunately the enthusiastic advocates for its correction have made the subject a highly controversial one, and yet all will agree that a proportion of women with this displacement have definite symptoms, which may be relieved by replacing the uterus in its correct position. It has long been recognised that during the puerperium the recent stretching of the pelvic tissues makes it easy for the uterus to assume an abnormal position, and that many cases of retroversion may begin at this time. Most of the standard text-books on obstetrics suggest that retroversion is only likely to occur if some predisposing cause arises during the puerperium, subinvolution of the uterus and retention of urine being the two most often mentioned. That this is not so a consideration of the present series will show.

### *Method of Investigation.*

This investigation was carried out in 1922 at the Greenwich Borough Council Maternity Home, and 122 consecutive cases were considered. Although this home was intended for all cases of labour, there was a rather high proportion of abnormal labours, as is usual in lying-in homes. The patients were, in most instances, admitted at the onset of labour, allowed out of bed on the 10th or 11th day, and discharged on the 14th or 15th day after labour. On the 13th or 14th day after labour a routine examination of the pelvic organs was made. The night before this examination an aperient was given, and immediately before it the bladder was emptied. If anything abnormal was discovered, arrangements were made for re-examination after an appropriate interval.

*Labours.*—Of the 122 cases 65 were multiparæ and 57 primiparæ. The following abnormalities were noted: 5 cases of contracted pelvis (1 treated by Cæsarean section, 4 by induction of premature labour), 1 severe accidental antepartum hæmorrhage, 2 cases of placenta prævia, 1 pregnancy complicated by fibromyomata of uterus, 1 pregnancy complicated by ovarian cyst, and various other less important complications.

During the puerperium every endeavour was made to avoid the occurrence of retroversion. The patients were sat up early, and great care taken to prevent retention of urine and to treat it early if it occurred. Special instructions were given to the nurses on the importance of not pressing the uterus backwards in the course of routine examination. At the postnatal examination the following abnormalities were noted: retroversion of the uterus, 8; subinvolution, 4; fibromyomata of uterus, 1; ovarian cyst, 1; pelvic thrombosis, 1. The cases other than retroversion are not considered in this paper, but it is of interest to note that they were all re-examined four weeks later, and in no instance was the uterus found to be retroverted.

As there is some difference of opinion on the subject, it may be well to give the following definition. A uterus was considered to be retroverted if the body was found lying in the pouch of Douglas. Minor alterations of position relative to the normal were not included under this term. Of the eight patients in whom the uterus was found to be retroverted, four were multiparæ and four primiparæ. The following were the only abnormalities noted in these labours: one anencephalic monster, one stillborn macerated fœtus (36 weeks), and one low forceps for uterine inertia. In every case the puerperium was afebrile. The standard of morbidity was a high one—namely, any rise of temperature to over 100° F. after the first 24 hours. In no instance did retention of urine occur.

### *Procedure Adopted at Postnatal Examination.*

If the uterus was found to be retroverted an attempt was made to antevert it bimanually. If this succeeded the patient was turned on to her face and remained lying in that position for two hours. The next day she was examined again, and if the displacement had recurred a ring pessary was inserted after anteverting the uterus. All cases in which any abnormality was noted were re-examined a month later.

The results of this procedure were as follows. In four cases anteversion was easily performed at the first attempt, and did not recur during the first six weeks of the puerperium. One case was similar, except that she was not examined until the 21st day of the puerperium on account of a perineal laceration. In one case in which some difficulty was encountered in anteverting the uterus a ring pessary was inserted at the first examination. A month later the position of the uterus was good, and the pessary was removed. After another month the uterus remained anteverted. In one case anteversion succeeded and at re-examination next day the uterus was still anteverted; when seen a month later retroversion had recurred. This was corrected and a pessary inserted, and subsequent examinations showed that the uterus remained in its normal position after the pessary had been in for two months. In one case all attempts at anteversion failed. This case was watched, but as no definite symptoms resulted, no further treatment was considered advisable. This simple procedure, therefore, resulted in seven successes and one failure.

### *Discussion.*

On examining the pelvic organs on the 14th day after labour a moderate degree of softening of the tissues was still present, the uterus was distinctly mobile. If during bimanual examination the uterus was gently squeezed in the majority of cases a little blood-stained mucus could be expressed through the cervix. In a certain number the amount of this fluid was increased up to about an ounce and the proportion of blood was increased. This was so in 14 cases in the present series. Although in five of these—four subinvolution, one fibromyomata of uterus—this was expected, of the remaining nine only one showed retroversion. These were all multiparæ, and clinically only two of them showed a corresponding alteration of the lochia. It is of interest to note that none of these cases, when examined a month later, showed a late retroversion.

### *Time at which Retroversion Occurs.*

Various writers have emphasised the frequency with which retroversion of the uterus occurs during the puerperium, but most appear to be of the opinion that the displacement does not take place so early as the end of the second week. Thus Prof. Whitridge Williams states "retroversion is rarely observed before the third week." He gives the total incidence as 20–25 per cent. Lynch, who has written probably the most exhaustive article on this subject, states that 41 per cent. of all cases showed retroversion of the uterus at some time during the 12 months following labour, 28 per cent. of this number were present one month after labour, the remaining 72 per cent. being discovered for the first time at some later date. Unfortunately this work was done before Lynch's article appeared, and so the importance of late retroversion was not appreciated. It may be noted, however, that none of the cases (15) examined later for some other condition showed this displacement. The degree of retroversion found in Lynch's series is not clearly defined.

At the end of the second week of the puerperium Webster gives the length of the puerperal uterus as 4 in., so that its size offers no theoretical objection to complete retroversion. That it can occur anyone may convince himself by bimanually retroverting a uterus, a manœuvre which can generally be done easily at this time. That the uterus will not stay in this position is interesting, and makes this little experiment justifiable.

The present series confirms the findings of other writers that no relation is found between the frequency of retroversion and the alleged contributory factors. Subinvolution, vaginal relaxation, multiparity do not particularly predispose, nor do the abnormalities of labour increase the incidence. No attempt is made to consider symptomatology in this short series.

### *Summary.*

1. Retroversion of the uterus occurs during the first two weeks of the puerperium in from 5–10 per cent. of all cases. 2. The incidence of this condition has no relation to the parity of the patient, type of labour, or abnormalities of the puerperium. 3. The displacement can easily be corrected, in most cases, by the simple routine described.

My thanks are due to Miss L. Beeham, matron of the home, for her help in this investigation.

# HYPERTHYROIDISM TREATED BY X RAYS.

## A RECORD OF THREE HUNDRED PRIVATE CASES.

BY A. E. BARCLAY, O.B.E., M.D. CAMB.,
D.M.R.E. CAMB.,
HON RADIOLOGIST, MANCHESTER ROYAL INFIRMARY,
AND
F. M. FELLOWS, M.B., F.R.C.S. EDIN.

A VAST and ever-increasing literature has grown up on the subject of hyperthyroidism, but "the explanations offered to elucidate the phenomena of thyroid disease are as a haystack of speculation in which the needle of truth is still at large" (Bram). The object of this short paper is not to add a new theory to the already bewildering collection, or even to attempt a résumé of the present state of knowledge (or lack of knowledge), but the comparatively modest one of recording the effects of X ray treatment on a series of 300 consecutive private cases of hyperthyroidism during the years 1912–23.

By hyperthyroidism is meant the pathological degree described by Parry, Basedow, Graves, &c., though all the cardinal signs mentioned by these authorities are not necessarily present in every case. A great number of cases have been, and are being treated by X rays, and much has been written on the subject. It has, nevertheless, been found difficult to ascertain the numbers treated and the percentage of recoveries.

In 1912[1] Florence Stoney recorded 41 cases and in 1921[2] a further report on 200 cases was presented. In 1920[3] Burrows and Morison gave the comparative results of 200 cases, half of which were treated by radium and half by X rays. These latter are included in the authors' compilation, and it is interesting to note that, after a lapse of five years, these results showed no relapses.

### *The Authors' Cases.*

These have been tabulated by one of us (F. M. F.), who has never been engaged in radiological practice. The paper is based on an experience of 2700 hospital and private patients. The tabulation of the 300 private cases was effected by taking the notes of all patients who had been discharged or who had ceased treatment. So far as we can tell, a larger number would not have altered the figures to any extent. The hospital results, however, would certainly come out in a much less satisfactory manner, for it is obvious that home conditions have an enormous influence on the chances of recovery.

The responsibility for the diagnosis rests on the physicians who referred the cases for treatment, a very large proportion of them having passed through the hands of Prof. G. R. Murray.

The results are as follows:—

| | Numbers. | Per cent. |
|---|---|---|
| Cured, or good functional result | 190 | 63·3 |
| Improved | 75 | 25 |
| Not improved | 15 | 5 |
| Lost sight of | 20 | 6·6 |
| Total treated | 300 | 100·0 |

Of these cases, 11 have since died from intercurrent disease and 8 from hyperthyroidism. The series of Burrows and Morison (loc. cit.) may be compared with these.

| | X rays. | Radium. |
|---|---|---|
| Perfect | 27 | 20 |
| Good functional | 49 | 20 |
| Improved | 20 | 40 |
| Not improved | 4 | 20 |
| | 100 | 100 |

Dr. Stoney's results do not differ materially from the above.

It was found difficult to separate the cases completely cured from those in which the treatment resulted in a good functional result, and we have, therefore, grouped them together. Many were really "cured" and were able to do everything they had been accustomed to do before their illness. Most of these were among the younger patients and where the disease had not been of long duration. The majority—"good *functional results*"—are able to lead a useful and moderately *active* life. Where the hyperthyroidism has led to *organic* cardiac disease, the damage to the heart is, of course, unaffected by the treatment.

The number of cases in which the disease could be attributed to a definite *exciting cause* was comparatively small. In a large proportion, however, dental and alveolar sepsis were discovered and invariably treated. We regard a dental examination as most important and usually radiograph the teeth in the course of the systematic examination of the patient. Cases with a local sepsis of this kind are not likely to improve beyond a certain point under treatment until it has been dealt with.

The *sex incidence* shows that there were 260 females (86·6 per cent.) and 40 males (13·3 per cent.).

The *age incidence* was as follows:—

260 Females.

| Age | 0-10 | 10–20 | 20–30 | 30–40 | 40–50 | 50–60 | 60–70 |
|---|---|---|---|---|---|---|---|
| Cases | 1 | 11 | 57 | 78 | 75 | 28 | 7 |

40 Males.

| Age | 10–20 | 20–30 | 30–40 | 40–50 | 50–60 |
|---|---|---|---|---|---|
| Cases | 1 | 3 | 12 | 18 | 6 |

There were six instances of hyperthyroidism running in families, two or more in a household having developed the disease. In one instance three sisters out of seven developed hyperthyroidism; two died, and the third was the only one to come under treatment. She is now in perfect health.

### *Symptoms.*

Of the cardinal symptoms (goitre, exophthalmos, palpitation, and tremor) the *goitre* was by no means constant, and was present in not more than three-quarters of the cases. It is usually general and involves the isthmus. The degree of hyperthyroidism bears no relation to the enlargement of the gland. *Exophthalmos* is also a variable symptom. It was noted as being present in 203 cases (68 per cent.) in the series. Both eyes are usually affected, but occasionally only one is prominent. The degree of exophthalmos varies greatly from the least prominence of one or both eyes to the well-known protruding eyes characteristic of an advanced case. A one-sided exophthalmos occasionally persists after a case is otherwise "cured," but it usually subsides in the end. *Palpitation*, associated with tachycardia, is the most constant symptom of the disease. The average pulse-rate, taken with the patient sitting down when first coming under treatment, was about 120; it was occasionally so rapid as to be uncountable. The type of the pulse at the wrist is peculiar, exhibiting a slight "nervous" tremor or thrill that is quite characteristic. This feature clears up as the patient's general condition improves, even though the pulse-rate at the time of examination has not gone down to any appreciable extent. *Tremor* is practically always present and was looked for in the hands only. It may be either fine or coarse. The former may be so fine as to be hardly appreciable unless the fingers are observed alongside some steady object. A patient with the coarse variety of tremor may be unable to raise a full cup of tea without spilling it. Tremor is much increased by exertion or excitement.

[1] Brit. Med. Jour., August 31st, 1912.
[2] Proc. Roy Soc. Med., 1921, vol. xiv.
[3] Ibid., 1920, xiii., 133–141.

*Nervousness* is a common, almost an invariable symptom, but is very variable in character; lack of confidence, and fear of traffic and of heights are often complained of, also irritability of a senseless type and lack of self-control. Tears are ready to flow without apparent cause, and the patient may suffer from a feeling of impending disaster. Mental instability is another feature, and from time to time border-line mental cases were noted; all but one of these recovered.

*Metabolism* is enormously increased, and the metabolic-rate test has been largely used in the U.S.A., and, to a less extent, in this country in estimating the severity of the disease and the effect of treatment. In our experience this test is inferior to the trained observation and judgment of an experienced physician.

*Loss of weight* in these cases is often very striking, It comes on gradually and may amount to 100 lb. The arrest of this loss of weight under treatment constitutes one of the most satisfactory signs of progress.

Hyperthyroidism begins insidiously, the patient feels " below par " and lacks energy, and a little later becomes conscious of the heart's action. The pulse-rate increases slowly. Then comes palpitation on exertion, and the pulse shows the characteristic nervous feature previously described. There is a diffuse apex beat and the left ventricle is enlarged. Examined radiologically, this enlargement is found to take place, in the first instance, backwards rather than outwards. It is therefore not apparent on physical examination. Under certain fixed radiographic conditions the normal measurement of the displacement of the shadow of the left ventricle is 14 mm. as a maximum when the X ray tube is moved 10 cm., but with enlargement a displacement of 25–30 mm. is common before there is evidence of any abnormality on clinical examination.

A few other points may be noted: Patients suffering from hyperthyroidism do not " catch cold," and an infection of this nature usually indicates that the treatment is beginning to tell. Neither do they feel the need of warm clothing in cold weather. Swelling of the ankles, not pitting on pressure, occurs with some frequency, and in a few instances this symptom alone has brought the patient under observation. Of other symptoms diarrhœa and loss of hair are the most frequent.

The association of *diabetes* with hyperthyroidism is more than a coincidence; we have had one case where two sisters had both hyperthyroidism and diabetes, and in about ten cases the diseases were coincident. Quite apart from diabetes, however, these patients very frequently suffer from abnormal thirstiness.

### *Method of Treatment.*

The X ray treatment of hyperthyroidism is no stereotyped and routine course. The radiologist takes full responsibility and must be prepared to adapt his methods to the individual needs of his patients. It is for him, and for him alone, to prescribe the dose of rays and the times of their administration. If he is to do this intelligently he must necessarily take a keen interest in the clinical picture that is changing before his eyes under the mysterious action of radiations that produce such definite results. He does not, however, undertake the treatment of the case except in so far as his own methods are concerned, the general treatment of the patient and the prescription of drugs being the province of the clinician in charge of the case.

Three types of radiation may be used: (1) radium; (2) deep X ray therapy with high voltage; and (3) ordinary X rays of medium wave length. Only the third method is described here, as the patients in the series under consideration were all treated in this way. After a routine examination, in which the salient points of the case are noted, the patient is treated lying down with the head turned to one side and a little raised. The rays are applied through a large oval localiser right down to the thyroid and including the whole of one side and the upper part of the superior mediastinum. The other side is then treated, the isthmus getting the overlapping dose from each side.

We use a filter of 3 mm. of aluminium and a layer of boiler felt between the localiser and the patient. The tube (Coolidge) is at a distance of 9 in. from the skin, and we use a 6–7 in. spark gap between points. We use 2 ma. running through the tube. The dose administered takes seven to ten minutes and is equal to one-third of an erythema dose on the skin. This can be given twice a week without danger, at any rate for a month.

At the end of two or three weeks we expect to find some improvement, and almost invariably do so. This may be manifested in a number of ways: (1) the patient feels better; (2) the pulse is slower, and, possibly, has lost its nervous character; (3) the irritability is not so marked. If we feel confident from any of these comparatively slight signs that the rays are beginning to act, the interval between the doses is increased to one week, and according to the patient's response to the treatment, we lengthen the intervals between the doses. As recovery progresses the intervals are extended to a fortnight, a month, three months, and finally six months, but no rule can be laid down, as it depends entirely on the patient's progress, and we often go back to more frequent doses if progress is not maintained or if the patient tends to slip back.

### *Results.*

The number of treatments necessary in each case is quite variable. The smallest number by which a patient was apparently cured was six. The average number is about 20, spread over a long period—it may be a year or more—but the patient is usually on the way to recovery after six to eight weeks. X ray treatment must be persisted with; the results are slow and progress is marked by " ups and downs " which recall the appearance of a typhoid temperature chart.

The first favourable sign is usually the loss of the nervousness with a gradually increasing brightness of outlook. This is accompanied by a return of energy and strength, and the patient is able to do a certain amount more. An atmosphere of optimism is thus engendered, and this is encouraged by the radiologist and is of the greatest importance in the treatment. The heart symptoms, like all the others, improve slowly, a fall in the pulse-rate being generally noticeable by the end of the fourth week, and there is a return of self-confidence for which the patient is very grateful. Slight retrogressions are common, and if the patient tries to do too much at one of these times a bad relapse may result. As a rule, however, these relapses are quickly overcome by increasing the frequency of the doses and by rest.

Gain in weight is a striking result of the treatment. The average gain where the patients were systematically weighed (80 cases) was 17 lb. Two cases, however, which were completely cured lost 3 lb. in weight. In some cases the gain in weight was sensational —e.g., a lady of 44 years, height 5 ft. 10 in., who was a living skeleton when she came under treatment and had to be carried in, weighed 61 lb. At the end of her course of treatment by X rays she was absolutely cured, the exophthalmos and goitre had disappeared, and she had gained in weight no less than 84 lb. Many other cases equally satisfactory but less striking could be cited. This increase of weight is sometimes so marked as to be distressing to the patient, but when we have seen such patients at a later date they are no longer worried on this account. If questioned, they will usually say that the weight gradually went down to normal as they resumed their usual activities.

Goitre and exophthalmos are two features of the disease which are very variable in their response to treatment, both often persisting long after the other symptoms have been relieved. One eye sometimes recovers before the other. In the end, however, these conditions tend to disappear, but quite a number of patients have gone back to full work with prominent eyes and neck, neither of which can be regarded as a criterion of progress.

Occasional treatments are given long after the patient is back at work and leading a normal life, the idea being to forestall any possible tendency to recurrence. Indeed, so convinced are patients of the good effect that X rays have on them that there is sometimes difficulty in getting them to accept their discharge.

In competent hands there are no risks. An X ray burn would almost certainly be due to ignorance or carelessness in administration. Persistence with X ray treatment before adequate filtration was practised resulted in the formation of telangiectases. In some five or six of the early cases these were very unsightly, the skin being largely replaced by thin scar tissue traversed by small vessels, although there had never been any question of an overdose producing a reaction. None of the cases that have come under treatment since 1910 have developed this trouble.

It is said that X ray treatment causes a fibrosis around the thyroid which interferes with its removal should the case come into the hands of the surgeon. This is, however, somewhat doubtful, as fibrosis is found in cases which have not undergone X ray treatment, or in which the treatment has not been sufficient to have had any effect on the thyroid.

Real recurrences are very rare. We have only had two or three and these have soon responded to treatment. Septic absorption from teeth, colon, or elsewhere and diabetes are the most likely factors causing tendency to relapse. Until this underlying condition is located and dealt with, recovery will be delayed. Abscesses about the roots of crowned teeth are responsible for many things.

When interpreting the effects of treatment one must remember how variable is the course of the disease. "Under similar treatment some cases improve rapidly, others fluctuate or lose ground, or die." A certain number of mild cases, moreover, recover completely without any treatment at all. It is, however, impossible not to be convinced that X ray treatment brings enormous relief to the great majority of those afflicted with this disease.

### *Summary.*

To recapitulate: We have in this method a means of restoring to a useful and moderately active life between 60 and 70 per cent. of patients incapacitated by hyperthyroidism. A further 20 or 30 per cent. will be greatly benefited in health. The cases considered in this paper are consecutive and unselected. Cases of the somwhat rare condition of acute toxic goitre seldom come under X ray treatment owing to transport difficulties. They are usually satisfactorily treated by radium. Under both radium and X ray treatment a fulminating type of acute hyperthyroidism has been noted, and has invariably been fatal. Two of the three deaths from hyperthyroidism in our series were of this type, the patient having made satisfactory progress up to a point, and suddenly developing acute symptoms and dying within a few days.

The method, though slow, is, in competent hands, pre-eminently safe. The results are permanent, and, so far as we are able to judge, at least as good as those of surgery. Collaboration, not rivalry, between physician and radiologist is the ideal to be aimed at, for each can do much for the patient afflicted with this disease.

# DIABETES AS SEQUELA TO ACUTE PANCREATITIS.

(*From the Diabetic Clinic of the Ministry of Pensions.*)

BY J. P. S. DUNN, M.B., D.P.H. DUB.,
D.M.R.E. CAMB.,
PATHOLOGIST;
S. VATCHER, M.B., B.CH. CAMB.,
RESIDENT PHYSICIAN;
AND
A. S. WOODWARK, C.M.G., C.B.E.,
M.D., F.R.C.P. LOND.,
VISITING PHYSICIAN.

NOTWITHSTANDING the extensive destruction of the pancreas that may ensue upon infection, the presence of glycosuria, and onset of diabetes, is the exception rather than the rule. It would appear, therefore, that in the majority of such cases a sufficiency of functioning tissue remains to ensure a normal metabolism of sugar. The experiments of Minkowski demonstrated that the survival of a small portion of healthy pancreas would suffice for this purpose. Again, the post-mortem table has shown us that a diffuse destruction of glandular elements may be unattended with glycosuria; that diabetes is, in fact, an occasional accompaniment only of associated pancreatic disease. The latter, in its chronic variety, is most frequently secondary to infection from the gall-bladder, the efferent lymphatics from which are in direct anastomosis with the lymphatics about the head of the pancreas. Thus cholecystitis is not uncommonly associated with a pancreatitis in which the phenomenon of glycosuria is absent. Such inflammatory change is manifest in two forms, designated extra- and intralobular, according as the resulting sclerosis affects the extra-lobular increase of connective tissue, or is mainly disposed among the acini, in the latter case the islands of Langerhans and the internal secretion being early impaired. Whatever the factor which determines the distribution of the sclerotic change, it is certain that the intra-lobular variety is of relative rarity; that in the majority of cases of pancreatitis glycosuria is a significant and late phenomenon. Thus in those infrequent cases of pancreatic lithiasis, in which an intense sclerosis is developed, in congenital syphilitic infection, and in that lipomatous condition rarely observed in connexion with cancer of the head of the pancreas, the entire glandular parenchyma may be crushed out of existence, or replaced by fat, while Langerhans' islands remain intact. It is not surprising, therefore, that diabetes is only occasionally noted as a sequela of acute pancreatitis,[1] a condition in which great portions of the gland may be extruded as sequestra. With the immediate clinical manifestations and causative basis of the acute infection we are not here concerned. Suffice it to say that the process is most probably initiated by a retrojection of infected bile into the duct of Wirsung, causing an activation in situ of tryptic ferments, with ensuing autolysis and necrosis of the glandular elements.

Of several hundred cases of diabetes which in the past two years have been admitted to this clinic, two only have been directly attributable to a previous acute infection. They are deemed to be of sufficient interest and rarity to merit a record.

### *Clinical Records.*

CASE 1.—Male aged 30. Prior to attack had enjoyed good health; *no history of gall-stones or of biliary infection.* In the month of February, 1916, while on a route march in France, he suddenly collapsed with acute abdominal pain. Operation was performed and acute pancreatitis diagnosed. A drainage-tube was inserted and the abdomen closed. Subsequent to this, though voluminous, "greasy," and fatty stools were noted, no symptoms were revealed. Patient gained in weight until the end of 1922, when prodromal symptoms—viz., loss of flesh, thirst, bulimia and polyuria—made their appearance. Medical advice was sought, and sugar was detected in the urine. He was admitted, therefore, to Leicester Hospital, his fasting blood-sugar being then 0·12 and urine-sugar 3 per cent. By means of careful dieting symptoms were relieved; body-weight, however, progressively diminished.

---

[1] Noceto: *Diabète Gras au cours d'une Pancréatite Aiguë Partielle*, Archives des Maladies de l'Appareil Digestif et de la Nutrition, *Février*, 1913.

On May 7th, 1925, patient came under our care. He was of healthy appearance and normal development. On admission blood and urine sugars were respectively 0·2 and 5·5 per cent. No acetone was present. The fat *content of stools was normal. Subsequent progress is* shown in table below.

| Date in May 1925 | CH. | P. | F. | Cals. | B.S. %. | U.S %. | Acet. | Ins. units. |
|---|---|---|---|---|---|---|---|---|
| 8th .. | 21 | 59 | 160 | 1760 | 0·09 | tr. | — | — |
| 15th .. | 50 | 60 | 146 | 1754 | 0·100 | — | tr. | — |
| 18th .. | 60 | 81 | 165 | 2049 | 0·160 | tr. | — | — |
| 20th .. | 60 | 81 | 165 | 2049 | 0·100 | tr. | — | 10 |
| 25th .. | 60 | 81 | 165 | 2049 | 0·100 | — | — | 10 |

From May 25th the caloric value of the diet was gradually increased until the patient was in receipt of 36 calories per kilogramme of body-weight. Pari passu the insulin dose was advanced to 30 units, distributed in two doses daily. Given prior to the morning and to the evening meal this quantum was found adequate to maintain the blood-sugar over the 24 hours period at a uniformly normal level. Chart 1 illustrates the effect upon the blood-sugar content of ingestion of 50 g. of glucose at a period when the fasting level had been reduced to the normal. As will be seen the curve indicates that defect of the storage mechanism characteristic of diabetes. Under treatment symptoms have disappeared. A trace of glycosuria is occasionally noted; the patient is otherwise, apparently, a normal and a fit man.

CHART 1.

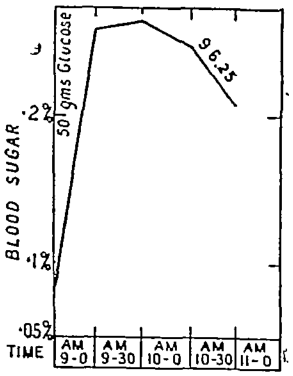

CHART 2.

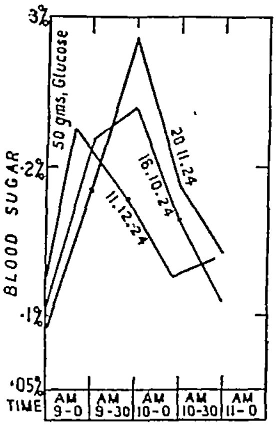
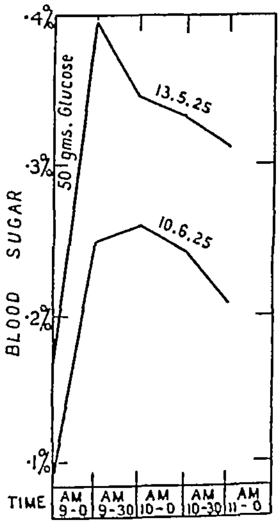


CASE 2.—Male aged 56. Patient of obese type (weight, 156 lb.; height, 5 ft. 4 in.). Family and personal history unimportant. Was admitted as an acute case to Middlesex Hospital in January, 1920. To the surgical registrar of that hospital we are indebted for the following particulars. "On admission, temperature 99° F.; pulse, 128. Abdomen distended and very tender on palpation, especially on the right side. Operation performed two days after admission. On incising the peritoneum an effusion of free blood was found in the peritoneal cavity. The appendix was normal, and the blood appeared to be coming from the retroperitoneal tissues of the posterior abdominal wall. A drainage-tube was inserted and the wound sutured. A specimen of urine was sent for examination. The diastatic power found—viz., 133 units—was very suggestive of pancreatic disease. Patient's temperature continued irregular—up to 102°, with decreasing amount of discharge from abdominal wound. On March 2nd a second examination was performed. An incision was made below the right costal margin and a large amount of sweet-smelling blood-stained debris and pus evacuated. A cavity was found in the region of the pancreas from which discharge appeared to be coming. A large drainage-tube was placed down to this cavity. On the 24th his temperature and pulse were normal. Patient was discharged to convalescent home on April 17th, 1920; abdominal wound was then practically healed. Diagnosis: Acute pancreatitis."

Subsequent to recovery from the operation the patient came under the observation of medical boards of the Ministry of Pensions. In August, 1922, in the course of a routine examination, a trace of sugar was found in the urine, together with albumin, and hyaline and granular casts. For September of the following year (1923) no sugar is recorded as being present; albumin, was, however, again noted. Urinary diastase was at this period normal. In August, 1924, the urine showed a glucose content of 0·6 per cent. and the fasting blood-sugar amounted to 0·18 per cent. On the latter account the patient was admitted to this clinic. At this time an unrestricted dietary was attended with glycosuria; on a slightly restricted diet blood-sugar variations were within normal limits. The urine contained a trace of albumin, no casts. Blood pressure was 180 systolic, 110 diastolic. No ketosis; diastatic index normal. The fat content of stools was normal. Sugar tolerance tests performed at intervals of several weeks showed graphs as given in Chart 2.

It will be noted that though the rise in blood-sugar following administration of glucose varies in successive curves, the curves themselves show a considerable conformity to type. Particularly in the test first undertaken was this of the "lag" species—a species in which the mechanism controlling storage "lags" behind that stimulative level of the blood-sugar—viz., 0·16 to 0·18 per cent.—at which storage is normally induced. The later curves, though less typical of "lag," were yet considered to be insufficiently characteristic to justify a diagnosis of diabetes; and as at this time no symptoms were apparent the patient was discharged. In view, however, of the anomalous nature of the graphs, and of the preceding history of acute pancreatitis, it was thought that an early degree of pancreatic inefficiency was signified; that the graphs were, in fact, indicative of the onset of diabetes. The patient was discharged, therefore, only for later observation. In January, 1925 (five years subsequent to acute infection), prodromal symptoms—viz., polyuria and polydipsia—were complained of; these speedily became more urgent until patient's readmission here on April 9th. Examination confirmed our previous views. At this date the sugar content of urine and fasting blood were respectively 4·0 and 0·16 per cent. The pre-insulin curve of tolerance and that derived in the course of treatment (Chart 3) indicate a marked degree of pancreatic inefficiency, and contrast in an interesting way with those obtained at an earlier period (Chart 2).

CHART 3.



Insulin therapy was initiated in the usual manner in small doses, commencing with 5 units twice daily, and the dietary was gradually increased to the caloric requirement of the patient, the insulin quantum being pari passu augmented. On discharge the patient was in receipt of 20 units, distributed in two doses daily; the blood-sugar throughout the 24 hours was uniformly normal; ketosis was absent; an intermittent trace only of glycosuria was observed. All symptoms of diabetes had ceased.

### *Conclusion.*

In concluding, we draw attention to the significant fact that recent radiograms, taken in the manner advocated by Carman[1]—viz., following (oral) administration of sodium tetrabromphenolphthalein—have given reason to suspect the presence of gall-stones in both of the above-detailed cases. Pancreatitis, acute and chronic, being most commonly secondary to infective process elsewhere, in view of a tendency—more pronounced since the advent of insulin—to find the ætiological basis of the individual case of diabetes in a pathological condition confined to the pancreas, we cannot too strongly emphasise the importance, both from the point of view of exact diagnosis and from that of treatment, of an X ray examination of the entire gastro-intestinal tract in every suspect case. Such a study will, it is hoped, form the subject of a later communication.

For permission to publish we express our indebtedness to the Director-General of Medical Services of the Ministry of Pensions.

# Clinical and Laboratory Notes.

## TWO UNUSUAL CASES OF
## CEREBRO-SPINAL FEVER.

BY EDWARD JAMES, M.B., CH.B. ABERD.,
SENIOR ASSISTANT MEDICAL OFFICER, PLAISTOW HOSPITAL.

THE following two cases of cerebro-spinal fever are of interest, the first because of the insidious nature of the onset, the second because of the early age at which it occurred.

A. F., female, aged 16, was admitted to Plaistow Hospital on May 23rd, 1925, under a diagnosis of typhoid fever. Her illness had begun about a week previously with generalised pains and abdominal discomfort. For three days before admission she had a temperature in the neighbourhood of 102° F., with a pulse of 100, and had complained of slight headache.

*Condition on Admission.*—The patient was mentally clear, though inclined to be drowsy. The temperature was 102·6° and pulse 116. The tongue was dry and covered with a brownish fur, while sticky sordes coated the gums and back of the pharynx. There was generalised abdominal tenderness, but no distension or marked rigidity. The spleen was enlarged and palpable. There was no rigidity of the neck, no ocular paralysis or sign of other cranial nerve involvement. Kernig's sign was absent, and the knee-jerks and plantar reflexes were normal. A loud mitral systolic murmur was present, but the heart-beats were strong and regular. There was no history of diarrhœa, and an enema on the day of admission gave a constipated result.

During the night of May 23rd she was at times slightly delirious, and on the following day complained of pains in all the limbs, but particularly in the region of the thighs and hip-joints. These pains were exaggerated on movement. The abdomen was still tender and Kernig's sign still absent; the Widal reaction was negative and a blood film showed a moderate leucocytosis. Despite the absence of any actual swelling of the joints the patient's condition at this time rather suggested acute rheumatism. On the 25th all symptoms were exaggerated and blood appeared in the urine. There was definite stiffness of the neck, but no head retraction, and Kernig's sign was now present. Lumbar puncture gave 10 c.cm. of slightly turbid fluid, examination of which showed many polymorphonuclear cells and a few intracellular meningococci. 75 c.cm. of polyvalent antimeningococcal serum were given intrathecally, intravenously, and intramuscularly in equal portions, and this was repeated next day. A purpuric eruption now appeared on the left ankle and buttock, becoming very profuse on all parts of the body during the next three days. Though delirious at times, the patient remained, for the most part, mentally clear. There was profuse diarrhœa, and the hæmaturia persisted.

On the 29th she became unconscious and very noisy, and died at 11.50 P.M. The temperature, which at first ranged from 102° to 104°, fell to 97·4° on the morning of the 29th, rising again to 103° just before death.

*Post-mortem Findings.*—The surface of the brain was extremely congested and there were extravasations of blood into the subarachnoid space. Patches of yellow, purulent exudate were present in the sulci of the cortex, but no pus was found at the base of the brain. The spleen was much enlarged and very friable; the kidneys were studded with hæmorrhages, and numerous purpuric areas of varying size were found throughout the small intestine. The myocardium showed several purpuric spots, and some were present also on the mitral valve, one cusp of which was markedly thickened and cicatrised. Both lungs showed some basal congestion.

The main points of interest in this case are: 1. The insidious nature of the onset and late meningeal involvement, though eventually, at least, the infection was of a virulent type. 2. The absence of cranial nerve paralysis, with which may be correlated the post mortem findings. 3. The occurrence of hæmorrhages in the heart muscle and intestine, no reference to which can be found in the ordinary literature.

J. D. Rolleston[1] quotes four routes by which the meningococcus may be able to reach the meninges—namely, (1) by the olfactory nerves and the cribriform plate; (2) through the sphenoidal sinus and bone; (3) by the Eustachian tube and middle ear; (4) by the blood stream, producing a general septicæmia, of which the meningitis is merely one of the manifestations. The last-mentioned route appears to have been that taken by the organism in this case.

The second case is that of a baby, who, on Nov. 3rd, 1925, when 7 weeks old, developed symptoms of meningitis and was admitted to Plaistow Hospital nine days later. Head retraction was by then well marked, Kernig's sign was present, and lumbar puncture gave a turbid fluid containing meningococci. The child is now drifting into the chronic state, with persistent vomiting, emaciation, and pronounced opisthotonos.

To illustrate the rarity of cerebro-spinal fever during infancy, Root[2] was able to collect only seven cases occurring in the first two months of life.

I am indebted to Dr. D. MacIntyre, medical superintendent, for permission to publish these two cases.

## A CASE OF
## SYPHILIS OF THE THIRD GENERATION.

BY W. KNOWSLEY SIBLEY, M.D. CAMB.,
PHYSICIAN TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

SYPHILOLOGISTS seldom experience the rarity of a congenital syphilis case which has missed a generation. Therefore the following history may be both instructive and interesting. The patient in question underwent a searching examination *re* the past history relative to his case.

In February, 1917, a patient was sent me by his doctor, who had been his intimate friend for many years. The patient himself was a man of the highest integrity and was scientifically interested in his own history. He was 55 years of age and unmarried. Five years previously to my first seeing him he had some ulceration on the tip of his nose and also some ringed patches on the abdomen and thighs, which after a time disappeared, leaving superficial scarring; the nose also greatly improved. When he first consulted me he had some rather deep ulceration on the right side of the face, in front of, and slightly involving, the lobe of this ear, which had been gradually spreading for some three years in spite of various local treatments. He also had some areas of pigmentation on the forehead, but little or no general adenitis, and the reflexes were normal. The external genitalia were normal. I diagnosed the condition as syphilitic, at which his own doctor was astonished, regarding it, from what he knew of the patient, as quite impossible.

[1] Carman, R. D.: Cholecystography in its Application to the Diagnosis of Cholecystic Disease, THE LANCET, 1925, ii., 67.

[1] Rolleston, J. D.: Acute Infectious Diseases, 1925.
[2] Root, J. H.: Amer. Jour. Dis. Children, 1921.

*History.*—The patient gave the following clear and definite history. He had never had coitus in his life, never having experienced the slightest desire for sexual connexion. His parents were first cousins, the fathers being brothers, one of whom, his paternal grandfather, who had led a dissipated life and was alcoholic, had died when under 40 from what was probably G.P.I. His own father died at 87 from senile changes, and his mother at 75 from stoppage of the bowels. Both were very healthy people. His maternal grandfather died at 70 from softening of the brain, and maternal grandmother, when about 70, from senile changes. The patient was the eldest of four children, and was born 18 months after the marriage of his parents; one infant was born jaundiced and died at 3 years of age from scarlet fever. His brother was an alcoholic, but his sister was quite healthy. He had an attack of typhoid fever at 21, and a nervous breakdown 20 years ago with so-called spinal irritation, but with the exception of a bicycle accident he has never suffered from any ailment.

The Wassermann reaction was strongly positive. I gave him a course of injections of hectine B, together with small doses of X rays to the ulceration. This was followed by a course of hectargyre B.

By the following June all the ulceration had healed and the Wassermann was negative. After this he took some mercurial pills for some months, and as far as I am aware he has had no return of his former symptoms.

The following points in the above history are of special interest. There appears to be but little doubt that the paternal grandfather was the originator of the disease. The parents of the patient were both very healthy, long-lived people, neither having ever shown any evidence of inherited or acquired disease. In cases of inherited syphilis it is generally assumed that the infection is conveyed by the mother to the fœtus. In the above case the infection I presume to have been conveyed by the germ inherited by the father to the ovum of the mother, and yet neither parent ever revealed any signs or symptoms of the contagion.

## A CASE OF
## PERICARDIAL EFFUSION OF TUBERCULOUS ORIGIN.

BY JOHN GRACIE, M.B., F.R.F.P.S. GLASG.,
SENIOR ASSISTANT PHYSICIAN, WESTERN INFIRMARY, GLASGOW.

THE following case of pericarditis with effusion appears to be worthy of record on account of the abnormally large effusion into the pericardial sac, and also on account of the absence of certain of the recognised signs of a pericardial effusion.

W. D., aged 49 years, a stonemason, was admitted to hospital on August 13th, 1925, complaining of shortness of breath and extreme exhaustion. His illness dated from the beginning of July when he contracted a "chill" after exposure to cold. This was followed by weakness and breathlessness. He continued to work for a week, but on account of increasing weakness, breathlessness, and a feeling of exhaustion he had to give up work and take to bed. His condition became steadily worse until his admission. With the exception of "gastritis" two years ago he had always been in good health. He was the father of seven children, two of whom died, one from meningitis and the other from pneumonia.

*Condition on Admission.*—When admitted the patient was very cyanosed and in a state of extreme exhaustion. He could not lie down, and in bed he assumed the position of orthopnœa. He was restless and anxious. His temperature was 101·6° F., respirations 30, pulse-rate 96 per minute. There was some distension of the jugular veins, but no visible pulsation. There was no enlargement of the superficial lymphatic glands and no œdema. The chest was somewhat barrel-shaped. There was no localised bulging. The interspaces were not well marked and there was no visible pulsation over the precordium, epigastrium, or in the episternal notch. The apex impulse was not palpable. Almost the entire front of the chest was dull to percussion, dullness extending diagonally from the sternal borders at the second interspace to the mid-axillary line at the level of the fourth rib on each side, the dull area thus outlined being pyramidal in shape. On the right side dullness merged with liver dullness, while on the left side the gastric crescent was clearly defined. Posteriorly the percussion note was slightly hyper-resonant. There was no dull area. The respiratory murmur over the front of the chest was inaudible except at the apices, where it was broncho-vesicular. Posteriorly it was harsh and accompanied by high-pitched râles. There was no evidence of effusion or congestion at either base. The heart sounds could not be heard over any part of the chest. The pulse-rate was 96 per minute, feeble and irregular, the nature of the irregularity suggesting auricular fibrillation. The arteries were thickened. The tongue was moist and thickly coated. There was no dysphagia. The liver dullness extended to one and a half inches below the costal margin in the mid-clavicular line and the liver was palpable and tender. The spleen was not palpable. There was no ascites. The pupils were equal and reacted to light. There was no abnormality in the nervous or urinary system.

The physical signs pointed to a large effusion into the pericardial sac, but the condition of the patient made an examination by radioscopy impossible. A needle was introduced into the pericardial sac at the fourth left intercostal space two inches from the left sternal border, and seven ounces of sero-sanguineous fluid were withdrawn. There was considerable pain and distress during the withdrawal of the fluid, and the patient's condition did not warrant a further effort at drainage. The left border of dullness diminished about one inch, but the right border remained unchanged. The heart sounds could be heard very faintly. There was no pericardial friction. Paracentesis gave slight temporary relief, but the patient gradually became more distressed. The pulse became more feeble and latterly imperceptible. Cyanosis became more marked, a dusky petechial rash appeared over his back, and there was dullness posteriorly at the base of both lungs. He died 24 hours later.

*Post-mortem Examination.*—The pericardial sac filled a large part of the thoracic cavity. It contained over three pints of sero-sanguineous fluid and the visceral and parietal layers of the pericardium were covered with a thick fibrinous exudate. The heart was not enlarged. The glands around the bifurcation of the trachea and the roots of both lungs show silicosis and healed calcified tuberculosis, also recent caseous tuberculosis. There was fluid in both pleural cavities. The lungs were partially collapsed, and they showed evidence of old-standing tuberculosis and silicosis. The liver, spleen, and kidneys were enlarged, the result of chronic venous congestion. The appearances suggested that the pericarditis was of tuberculous origin.

### *Discussion.*

The physical signs of a pericardial effusion necessarily vary in accordance with the amount of fluid contained in the sac. Ordinarily it does not exceed 16 oz., though in cases reported by Corvisart it reached 30–40 oz. The abnormally large quantity of fluid in the above case—viz., 60 oz.—would account for departure from some of the recognised physical signs, notably: (1) The extension of dullness to the right mid-axillary line which was probably accounted for by the absence of adhesions between the pericardium and the anterior thoracic wall allowing the pericardium to expand equally in both directions. 2. Absence of Sibson's notch in the left border of dullness. 3. Areas of absolute and relative dullness were approximately equal, accounted for by the distended pericardial sac filling up the entire front of the thoracic cavity, the lungs being displaced to the back with the exception of a small portion of the apex of each lung. 4. Absence of dullness at the base of the left lung (Pins's sign). 5. No evidence of pressure on the œsophagus, trachea, or recurrent laryngeal nerve. On palpation of the heart, post mortem, before any fluid was withdrawn from the sac, it could be felt floating upwards, the position of the apex corresponding approximately with the third left intercostal space. Further, a large quantity of fluid could be felt anterior to the heart, which confirms the view that the heart is suspended in the liquid and that it does not float on the surface, as stated by other observers. This would explain the entire absence of visible or palpable pulsation over the precordium.

---

NORTH WALES NURSING ASSOCIATION.—At the annual meeting of the North Wales Nursing Association, which was held at Bangor on March 5th, it was stated that there are now 98 district associations working under the scheme. In Anglesey there is a nurse to 1076 of the population; in Carnarvonshire one to every 2660; in Denbighshire one to every 2973; in Flintshire one to every 3090; and in Merionethshire one to every 2170. The new Government regulations for the training of midwives provide for only £350 from the education authorities and the Board of Education and £170 from the Ministry of Health, whereas formerly the corresponding contributions were £700 and £200 respectively. An appeal to the Ministry of Health to reconsider its grant is being made.

## ROYAL SOCIETY OF MEDICINE.

### COMBINED SECTIONS OF SURGERY, MEDICINE, ELECTRO-THERAPEUTICS, AND THERAPEUTICS.

(*Continued from p 552*)

### TREATMENT OF EXOPHTHALMIC GOITRE.

THE discussion on the treatment of exophthalmic goitre was resumed on March 9th, Sir Lenthal Cheatle, President of the Section of Surgery, occupying the chair.

### *General Management and Indications.*

Prof. F. R. Fraser said that, the cause of the disease being unknown, no treatment directed at the cause was possible. Recent developments, however, had made it advisable to review the situation so as to improve the general management of cases. These developments were the reintroduction of the treatment by iodine, the recognition of thyroid disease as a cause of auricular fibrillation and heart failure, and improved skill in the surgery of the thyroid gland, and in the selection and preparation of patients for operation. He again insisted on a differentiation of the cases into groups, setting out their characteristics, and said that the differentiation between primary and secondary groups was of importance in regard to both treatment and prognosis. Adolescence, pregnancy, the puerperium, and the menopause appeared to be dangerous events in both forms, and might be associated with increased intoxication; while septic foci in tonsils, sinuses, &c., if overlooked and not dealt with, were frequently responsible for exacerbations and relapses.

For the best management of a case one must have a clear knowledge of the natural course of the disease, and social possibilities entered largely into success. Over a large series of cases treatment by X rays and treatment by lobectomy produced a general result differing but little from the course of control cases not subjected to these measures; but "subtotal thyroidectomy" had a beneficial effect in comparison. In 60 cases of all forms of Graves's disease which were under the care of the medical unit of St. Bartholomew's Hospital tonsillectomy was performed in 14 on account of gross sepsis, and in each case there was a lower level of intoxication after the operation.

At present there was no clear indication as to the value of any special diet in the disease. He had no experience of the treatment of the disease by X rays or by insulin. If treatment were carried out on the lines indicated most of the cases of Graves's disease made a satisfactory recovery and returned to normal conditions of life and efficiency. A number of cases had been unable to carry out the treatment, a main cause having been heavy domestic responsibilities and worry when absent from home. If at the end of six months of rest and general measures the pulse-rate remained above 100, or if auricular fibrillation or other cardiac trouble developed, operation should be considered. Of the 60 cases in the hospital during the last five years, of the primary form 18 received no surgery and 8 of these were now doing well, 3 were slowly improving, 2 were doing badly, 2 were dead, 2 had been lost sight of. Of 14 operated on 1 died immediately after; the other 13 were now satisfactorily doing their work. Of 23 cases of secondary Graves's disease 10 were treated on general lines and 5 were continuing satisfactorily, 1 was doing badly and had now developed auricular fibrillation, 1 was lost sight of, and 3 died before they could be brought into a state satisfactory for operation; 13 had had thyroidectomy operations, 1 had recently died in hospital when readmitted for a further thyroidectomy two years after lobectomy. The other 12 were doing well. Ten of 14 primary cases were operated upon because they had to return to work as soon as possible; of the secondary cases 8 were operated on because of cardiac disturbances, only 1 for economic reasons. He urged the continual coöperation of surgeon and physician in order to secure the maximum benefit.

Mr. T. P. Dunhill directed his attention to the following points: How cases were selected for operation, how operation could be rendered safe and effective, the death-rate, the end-results. He made it clear that he did not regard operation as the one and only treatment for every stage of the disease, though for some stages it was the main one. Of the 831 cases on whom he had operated for exophthalmic goitre he had analysed the histories of 170 consecutive cases. Sixty-eight of them had been ill over four years, 48 over six years, 37 over eight years, 32 over ten years Mental disease in these patients was not uncommon; 11 were approaching a stage when they could not be looked after in their own homes; it was advisable to be in touch with a mental specialist about these. Only 1 of the 11 had not improved, and she had been in an asylum before. Chloroform he regarded as an unsafe anæsthetic in these cases; the best was gas and oxygen with a little ether, given by the intratracheal method. When auricular fibrillation was present he thought local anæsthesia greatly preferable

### *X Ray Treatment.*

Dr R W. A. Salmond said he regarded X ray treatment, though valuable, as subsidiary to both medical and surgical treatment. The most favourable type for the application of the rays was that with the classical Graves's syndrome of moderate acuteness. The earlier in its stage the case was secured the easier it was to treat. In most of the cases so treated in his purview there had been marked improvement. There seemed to be no means of ascertaining beforehand how a given case would respond to the rays. The most obvious effect had been an improvement in the patient's general condition, a less "nervy" condition, a disappearance of palpitation and tremors, and a steady fall in the pulse-rate. Each case should have its appropriate dosage, no general line could be laid down, and it must never be forgotten that a very potent agent was being used, which was capable of doing great harm. Filtration through at least 3 mm. of aluminium should be carried out. A too prolonged treatment might lead to atrophy of the gland Worries and fretfulness were found to counteract the good effects wrought by treatment. There was no reason why irradiation should not be associated with medical treatment.

The Chairman said though Dr. Salmond had made out a good case for treatment of exophthalmic goitre by X rays he did not himself like operating on a case which had been subjected to the rays, as it rendered the operation more difficult; the gland seemed to be more adherent to surrounding structures than normal. Neither was he a great believer in the value of X rays in the treatment of the disease. In America the chief function of the physician was apparently to prepare the patients for operation. Some in this country considered operation for the condition was quite unnecessary. In these discussions finality was not likely to be reached, but it was only by such discussions that the profession could appreciate how much—and how little—it knew.

Prof. G. R Murray spoke of the great value of such an intensive study of cases as had been carried out by the medical unit at St. Bartholomew's Hospital. He reminded Fellows of the important clinical studies of a group of cases of the disease which were made some years ago by Dr. A. Maude when he was in practice at Westerham; his papers giving the results were a model of good work. Prof. Murray's own experience of these cases had been gained in hospital and in connexion with patients seen in practice. He did not agree with Barker, in America, that under any treatment cases would recover in two or three years; that had not been his own experience. He had found an enormous difference in the duration of the disease in different persons. He considered that the secondary form of Graves's disease was much less common than the primary form. In a series of 300 cases in 11 years 288 were primary, 12 secondary. But the division was not a sharp one, and while there appeared to be intermediate cases, some which at first seemed to be simple thyroid intoxication later became more marked and developed into full Graves's disease. It was true that the cause of the disease was not known, but he wished to stress the causal importance of emotional strain. In his 300 cases there was a history of sudden shock in 38, prolonged anxiety in 17, so that emotion played a definite part in 18 per cent. And he agreed as to the importance of sepsis, and how much more hopeful treatment was when cases were brought under treatment at an early stage. He particularly urged those in private practice to be on the look-out for the early indications, and to be less prone to say such cases were neurasthenics. The value of X rays could not be doubted, but it must always be remembered that the disease was one of long duration. The effects of iodine in the disease he regarded as no more than transitory; he did not care very much for it as a routine measure.

Dr. DOUGLAS WEBSTER spoke on the radiological treatment of the disease, remarking that radiologists saw a worse type of case than did general practitioners. Of 107 cases he had treated in this way 88 showed marked improvement. He complained that some recent works failed to show an up-to-date knowledge of the progress made by the science of irradiation and the results it was accomplishing.

The discussion was concluded on March 10th, when the chair was taken by Dr. HUGH THURSFIELD, President of the Section of Medicine.

### *Electrocardiograph Indications.*

Dr. JENNER HOSKIN based his contribution on an examination of 130 cases of primary and secondary Graves's disease, both clinically and electrocardiographically, during 18 months. Only ten of the patients were males, and the ages of the patients ranged from 13 to 60. Fifteen of the patients were treated medically, and nine had a serious condition of the myocardium. In 49 per cent. of the cases the myocardium was healthy, in 51 per cent. it showed definite damage. Of those with a healthy myocardium 56 per cent. were under 30 years of age, whereas of those who had a damaged myocardium only 28 per cent. were under 30 years. Thus it was evident that operation was conducted under more favourable circumstances in the earlier decades of life, and it seemed inadvisable to persist very long with medical treatment in cases which did not readily respond to it. The heart condition seemed to be dependent on the severity of the disease and its duration, and a moderately severe condition lasting a long time appeared to have a greater and more lasting effect than did a severe one of short duration. Tachycardia, causing a tumultuous activity of the heart, was followed by fatigue and dilatation, murmurs at the apex and the base, and a basic friction rub. The hearts were most damaged in the cases of secondary Graves's disease which had been long-lasting. Dr. Strickland Goodall had stated that in primary Graves's disease the blood pressure was low, but in *the majority of the speaker's cases* the pressure ranged between 130 and 160 mm. Secondary Graves's disease showed a relatively higher blood pressure than the primary. In primary grade cases the electrocardiogram curves were normal in direction and amplitude, whereas in the secondary disease the curves were altered in many cases, and the heart-beat rate was less than in the primary form. He agreed with Dr. McNee that the pulse-rate afforded a very fair criterion of the amount of thyroid activity. He considered that a systolic blood pressure of over 160 needed that the patient should have either preliminary rest in bed with primary ligation or a modified enucleation, dependent on the degree of intoxication. Auricular fibrillation occurring late in secondary grades of long duration was not, per se, any contra-indication of operative treatment, but it was advisable for ligation to be done first, as also when the basal metabolism rate remained at over +50 in spite of rest and the administration of iodine. Marked changes in the electrocardiogram showed a toxic state of the heart muscle; he then advised a few weeks in bed, or primary ligation. Even *after this ligation* much improvement occurred. He showed and demonstrated a number of electrocardiograms of goitrous cases.

### *Discussion.*

Mr. LIONEL NORBURY said he attached great importance to primary ligation in some severe cases of exophthalmic goitre which had marked cardiac changes. It certainly, in his view, made the subsequent operation much safer. He examined the arguments for and against the procedure, and quoted cases in which primary ligation had been of real benefit.

Dr. W. LANGDON BROWN suggested that Dr. Ryle should try both optimism and iodine when dealing with cases of exophthalmic goitre. He felt that there was a good deal of truth in the remark that this disease was largely a matter of "sex and sepsis"; when women had a septic focus and an emotional strain was added they were liable to break down and manifest this syndrome. He quoted two cases in which patients experienced a set-back on visiting days at the hospital, due to emotional stress. In the matter of sepsis, he had been impressed by the importance of tonsillar sepsis in the disease. To stabilise a patient's weight he frequently had recourse to insulin; also in cases of anorexia nervosa in which the loss of weight was pronounced. A pulse-rate well over 40 usually indicated that the basal metabolic rate was increased, though the converse was not always true.

Dr. J. W. MCNEE referred to a specimen, in University College museum, of a fœtus showing an enormous thyroid gland, very prominent eyes, and other features of exophthalmic goitre, from a mother who had the disease to a marked degree. One could get a warning of an impending crisis in this disease by keeping a watch on the pulse-rate, for a sudden increase of this was a danger signal. If such a patient was not taking iodine it should be given; if she was having it, by increasing the dosage the crisis would probably be averted. He asked how frequently, since the reintroduction of the iodine treatment, Mr. Dunhill had found it necessary to do two operations on the gland. He had the idea that one lobe and a good part of the other could be removed at one operation, and if so, that seemed desirable, especially as it was a difficulty to have to tell a patient she must undergo a further operation.

The CHAIRMAN referred to the recurrent goitrous symptoms seen in young women at times of lactation, and asked for further light as to the indications for the use of insulin in the disease. He also asked whether X rays had been applied after the first operation.

Dr. E. G. CALVERT was asked to deal with the insulin question. He said he used insulin in these cases because of the antagonistic action between the insulin and the thyroid secretion. Insulin controlled the hyperglycæmia; its use often meant removing the burden from the protein metabolism and placing it on to carbohydrate metabolism; in other words, taking the strain off the thyroid and placing it on the pancreas. He had averted a serious crisis with mania by giving insulin, though after the crisis was past the effect of the insulin did not seem so great. Then iodine was given. He had found that most cases of exophthalmic goitre had hyposecretion in the stomach, and insulin caused the gastric secretion to increase and the appetite was improved.

### *Replies.*

Prof. FRASER expressed his appreciation of Dr. Calvert's statement concerning insulin. He still hoped some dependable *differentiation* of types would be arrived at soon, as until that was done there could be no real comparison of notes, nor any material advance in differential treatment. He would welcome further electrocardiographic investigations in this disease, the prolongation of the P.R. interval in goitre seemed, according to Dr. Hoskin, to show intoxication of the heart muscle. He pointed out the influence of life's sex events in determining at least exacerbations in the disease.

Mr. DUNHILL also replied. He said a valuable feature in this discussion had been the way in which surgeons and physicians had recognised the need of each other's help in dealing with the disease. Even when seen early, the circumstances of some patients were such that they could not derive the full benefit from treatment. He did not consider that operation was the treatment at every stage of the disease, but only for cases which had not responded to other measures. If he saw a patient within three months of the onset of symptoms he would on no account operate on her then; he would recommend her for medical care, so that her sepsis could be dealt with and the factors at work in her case ascertained. Moreover, at any time within six months the condition of the patient might become worse, therefore operation would not yield the best results if done before six months had expired. He admitted that the primary ligation referred to and carried out by Mr. Norbury might supply all that was needed to turn an early case to a favourable issue. In answer to Dr. McNee's question, in 700 of his 800 cases he had done two operations. It was necessary to observe an interval of about 12 days between the first and the second operation, so as to see what was the actual improvement brought about by the first operation. In one case, that of a fireman on an engine, he was well and back at work after only one operation. Most people, however, required the second lobe to be operated upon. In severe cases of the secondary type the second operation should follow the first as soon as possible.

Dr. SALMOND, replying on the comments made as to treatment of the disease by irradiation, said he agreed with Prof. Murray that very large goitres did not do so well under X rays as did those of moderate size. But he did not agree that radium was more stimulating to the gland than X rays in acute cases; moreover, radium might be preferable because its application did not involve disturbing the patient, whereas for X ray applications removal from bed had to be carried out, and a further disadvantage was the noise made by the apparatus. Over-enthusiastic use of the rays might cause a condition of arthritis of a joint, probably due to the absence of thyroid secretion in the metabolism. He agreed with Dr. Webster that the techniques employed in administering X rays varied a good deal; and the association in the disease with a persistent thymus which Dr. Webster mentioned was not sufficiently recognised.

## SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A NUMBER of short communications were made to the meeting of this Section held on March 4th, with Dr. EARDLEY HOLLAND, Vice-President, in the chair.

Dr. HERBERT SPENCER read a note on

### *Carcinoma Adenomatodes Cervicis Uteri.*

He remarked on the rarity of the condition, saying that confusion had arisen through the use in some works of the terms "adenoma malignum" and "adenoma destruens" for adeno-carcinomatous cases, in which at least part of the lining epithelium was proliferated. "Adenoma malignum" was a bad term, since adenomata were essentially benign growths. He had only met with one cervical case. This occurred in a woman aged 49, who had had four normal labours and one miscarriage. Menstruation had been regular, though profuse, except for two occasions when travelling. There had been no coitus for some years. About four years before the illness she had begun to lose more at her periods and once bled for three months, another time having six weeks without loss and then a severe hæmorrhage. For two years she had had a watery discharge which had twice smelt offensive. A piece of her growth had been diagnosed as an innocent adenoma by Mr. Targett, of the Clinical Research Association. Dr. Spencer removed the uterus with the Pacquelin cautery. It measured 10·5 × 6 × 4 cm., and the body was normal; the cervix was enormously enlarged by a growth infiltrating both lips. Microscopically this growth was composed of tubules and spaces, some dilated and filled with secretion, lined throughout with a single layer of cubical or columnar epithelium. The stroma was infiltrated with small round cells. The patient had been perfectly well for 22 years since the operation. The cases described by Cullen were adeno-carcinomata, not carcinoma adenomatodes, in which the simple appearance and absence of proliferation of the epithelium provided the chief pathological and practical interest. It was essential to examine large areas before claiming that there was no epithelial proliferation.

Dr F. J. McCANN referred to a case described in his "Cancer of the Womb." He thought the term "malignant adenoma" a good one.

Mr. H. F. SYMONDS described a method of

### *Endoscopic Examination of the Uterus,*

with its indications. He said that Reuben's method of insufflation with carbon dioxide was unsatisfactory because the inflation was contra-indicated in acute and subacute inflammations of the adnexa and cases of purulent discharge. Moreover, gas was unnecessary, since the uterine walls were rigid enough not to collapse on the tube. He had therefore had constructed a three-way brass tube on the lines of Chevalier Jackson's bronchoscope. It was 28 cm. long, with a 2-volt light, run from a dry battery, at the distal end, which was bevelled at an angle of 45° and carefully rounded off. Two of the channels were for suction; one of them could be used for irrigation or to run in adrenalin solution if required. They were connected with a bottle in which a partial vacuum was maintained by an electrical suction apparatus, and this kept the field free of blood and mucus. A small swab on a special holder was used as an obturator and might be put in three or four times during the examination, if required, to clean the lamp. There were two models, one with a 9 cm. bore for general use, and the other with a 6 cm. bore for small or atrophic post-climacteric uteri. A glycerine tampon was placed against the cervix for two nights and the cervix dilated slowly under general anæsthesia to 9/12. Direct vision of the endometrium could then be obtained and a piece could easily be removed for microscopy.

Mr. C. LANE-ROBERTS described a case of

### *Pregnancy Complicated by Ureteric Calculus.*

The patient was a primipara aged 27. At the fourth month of pregnancy she had a slight attack of pyelitis. At 7½–8 months (July 25th) she had pain in the back, œdema of the ankles, legs and thighs, and diminution of urine. On July 26th she had nausea and headache and passed no urine. On the 28th she was admitted to hospital looking and feeling pretty well, but still with suppression of urine. On the 29th she was catheterised at 2 A.M. and one ounce was withdrawn. At 11 A.M. she was examined and X rayed, with no result. Her blood pressure was normal and her blood-urea 96 mg. per 100 c.cm. Cæsarean section was performed, as it was thought that there must be a fibrous stricture aggravated by the pressure of the gravid uterus. A 30 weeks child was delivered and survived 36 hours. The right kidney was one and a half times its normal size, and the ureter distended nearly down to the pelvic brim. The left kidney was very large but its ureter normal. No obstruction was found and the abdomen was closed. Six hours later, as there was still no urine, a cystoscopy was performed and the right ureteric catheter passed up 4-inches only, the left into the pelvis. A right pyelotomy produced a large quantity of urine from a large, pale kidney, and the blood-urea fell steadily from 112 to 60 three days later, but no urine was passed by the bladder until the seventh day. Thus the reflex anuria of the apparently normal left kidney had lasted 11 days, even after the relief of obstruction. Cystoscopy on the twenty-fourth day showed cystitis, both ureters working well. Six weeks later a third X ray showed a small triangular shadow just above the bladder. Subsequently the patient had a perinephritic abscess from which she recovered, and a laparotomy later revealed a calculus in the pelvic part of the right ureter. Recovery was uneventful.

Dr. G. **Strachan** read a short communication on

### *Vaginal Polypi in Infants*

with a report of two cases. The first case was that of a female aged 18 months, perfectly well but for occasional spots of blood on the clothing. A firm, non-ulcerated semi-pedunculated polypoid mass about the size of a raspberry was found growing from the anterior vaginal wall about half an inch above the meatus. The vaginal orifice was dilated to take the tip of the little finger. Case 2 was an infant aged 5 months, with no symptoms save a " lump " noticed by the mother. A firm smooth mass about the size of a cherry was attached by a fairly broad base to the same part of the vagina. Both cases made an uneventful recovery after removal of the growth, cauterisation, and packing. Both tumours were red and congested and had an intact layer of squamous epithelium of varying thickness with occasional finger-like projections between the papillæ of the stroma. The main mass was composed of loose embryonic fibrous tissue, fairly infiltrated with lymphocytes. The blood-vessels were plentiful and well formed. There was no appearance of malignancy. Mr. Christopher Martin had suggested that remains of the original vaginal septum might be the origin of these tumours, their site being also that of most vaginal fibromyomata. The condition appeared to be very rare.

Dr. **Gibbon FitzGibbon** remarked that he had met two cases but neither had such large polypi. He then read a paper on a revised conception of

### *Antepartum Accidental Hæmorrhage.*

He defined some of the points in the generally accepted views of accidental hæmorrhage which he found incompatible with his clinical observations. The division into revealed and concealed hæmorrhage did not group the cases in any way connected with the gravity of the symptoms or the origin of the hæmorrhage. He accepted the opinion that the condition was due to a toxæmia and considered this supported by his clinical observations, but the toxæmia was either not the same as that associated with eclampsia, or else it had some fundamental modifying character. He considered that it arose from renal insufficiency and was a complication that arose during pregnancy in a subject of chronic nephritis. The various treatments adopted and practised with the object of controlling active hæmorrhage had not justified themselves by their results, because the bleeding was never really active or rapid in the serious cases, since it was due to a slow extravasation of blood from the whole uterine interstitial tissues, while in those relatively rare cases primarily due to ablation of the placenta the hæmorrhage, although sharp for a time, rapidly ceased by the normal process of coagulation and closure of the maternal placental sinuses and never gave rise to systemic symptoms. Antepartum accidental hæmorrhage must be divided into two types—a simple type truly accidental and due to ablation of the placenta, and a serious type due to toxæmia and interstitial degeneration of the whole uterine tissue without damage to the muscular elements. This type was better described as hæmatoma of the uterine walls, or uterine apoplexy. The symptoms were due to a slow progressive loss of blood, and the acute symptoms developed when that loss of blood had exceeded the physiological limits of vasomotor compensation, or when the onset of active labour added a greater strain than the depleted system could support. This latter was the common termination and required restoration from the condition of collapse; it was then usually followed by a rapid spontaneous termination of the pregnancy by the natural forces. The treatment and results from treatment in two groups of cases treated in the Rotunda Hospital during consecutive periods of nine and six years respectively were compared, as well as the pathological conditions found associated with the complication at operations and autopsies and reported by other observers, the general characteristics being almost universally the same. Active treatment to control the hæmorrhage was never required, but rather the restoration of the collapsed circulation. This was best obtained by the most conservative methods, after which the pregnancy could be terminated slowly by induction of labour in those cases which did not terminate spontaneously as a result of the complication, and which were not due to a purely accidental hæmorrhage as distinct from the diseased condition due to a toxæmic degeneration of tissues. The very serious cases commonly considered only amenable to operative treatment, such as hysterectomy, were not capable of standing the additional strain of such an operation, while those that recovered after operation would have been all the more easily treated for the collapse and would then have been suitable for simpler methods of terminating the pregnancy, if it had not ended spontaneously.—A brief discussion followed and some questions were asked.

Dr. G. W. **Theobald** then made a plea for

### *Drastic Reforms in the Teaching and Practice of Midwifery.*

He commented on the statistics of maternal morbidity and mortality, and maintained that many of the operations of gynæcology were the result of bad midwifery. Money and effort had been spent on the control of midwives and the establishment of antenatal centres, but the improvement was small. The midwife was expected to know too much, the doctor was getting less experience in normal midwifery, and the clinics had made possible an enormous amount of meddlesome interference. He illustrated his thesis by a résumé of cases admitted to the Leeds Maternity Hospital where at least nine women died during 1925 as a result of bad midwifery. Universities and teaching authorities shared the responsibility for these results. Many doctors had admitted to him that they had had to learn what midwifery they knew at the expense of their patients. It was, he said impossible to learn midwifery under the present hospital system. He pleaded for three or four hospitals and schools of midwifery in England on the lines of the Rotunda in Dublin, with a well-trained resident to supervise every detail of routine, where students could learn practical conservative midwifery " by osmosis." It was surely reasonable to claim that no operation other than low forceps should be carried out in a private house. Midwives should be forbidden to make a vaginal examination; the required information was obtainable by abdominal or rectal examination. He had not been able to find a single case of fatal sepsis in a woman who had not been vaginally examined. The remarkably low maternal morbidity in the Leeds Maternity Hospital he ascribed to a minimum of interference, free use of 1/1000 biniodide of mercury, abolition of binders, free purgation, and the administration of 40 c.cm. of antistreptococcic serum to all contaminated patients. Out of 35 primiparæ delivered by " the Garden of Eden method "—i.e., without any attention whatever from the nurse, who stood at a distance from the bed—18 had no laceration of the perineum whatever. Of 80 primiparæ delivered by the " modified Garden of Eden method," wherein the nurse simply prevented the head from being " born with a flop," 63 had intact perineums. Nor should the fundus be touched during the third stage.

Dr. J. S. **Fairbairn** cordially agreed with Dr. Theobald. The public must be educated, as the great difficulty of the general practitioner was the pressure from friends of the patient.—Dr. **Strachan** emphasised the time difficulty; general practitioners undertook far too many cases. Midwifery was going to midwives because the doctors did not want it.—Lady **Barrett** agreed that high forceps outside an institution should be forbidden, and that students should be taught to abstain from interference with the head or with the *uterus post-partum and to use safe drugs* for the relief of pain. The supervision of the junior student by a really competent teacher was most important.

Dr. THEOBALD, in reply, emphasised the value of scopolamine at any period of labour; he had never known it cause fœtal distress.

## BRITISH PSYCHOLOGICAL SOCIETY.

### *The Definition and Diagnosis of Moral Imbecility.*

A JOINT meeting of the medical and educational sections of the British Psychological Society was held at the house of the Royal Society of Medicine on March 8th. Five opening papers had been published in the *British Journal of Medical Psychology* a few days previously, and their writers spoke on special points only, after which the meeting was open for discussion.

Dr. A. F. TREDGOLD said that the definition of moral imbecility was inserted in the Mental Deficiency Act because, when the Royal Commission sat 20 years ago, a number of medical men gave evidence of the existence of a class of people characterised by anti-social habits, whose mental deficiency was such that they could not be certified as feeble-minded. Moral imbecility was a rare condition, but it existed, and its definition described the group of people with considerable accuracy. Confusion had, however, arisen because of attempts to include in the category cases of psychoneurosis and mental disorder. The psychological basis of a moral imbecile had two main characteristics: (1) antisocial propensities more marked than usual; (2) the ordinary inhibitions—wisdom and moral sense—less marked than usual. There was no such thing as inheritance of qualities, but only of tendencies; the absence of any tendency towards a moral sense, shown by the fact that it never developed at all, was the special mark of a moral imbecile.

Dr. CYRIL BURT did not believe in the existence of a moral sense as usually defined; if a defect in potentiality was meant it would be more correct to describe it as a temperamental defect. Intelligence was inborn though not present at birth; moral sense was acquired by training and not inborn at all. He did not think the necessity of proving an early history of deficiency should be insisted on; the impossibility of fulfilling this requirement prevented the certification of undoubted mental defectives. The two definitions of the mentally deficient and the moral imbecile appeared to be identical in meaning, and he suggested that the latter should be abolished.

Dr. M. HAMBLIN SMITH denied the existence of a moral imbecile altogether; he had long desired to see such a person but had never done so. Al the alleged cases could either be certified as feeble-minded or belonged to the category of psychoses or mental conflict. He regarded the definition as not only superfluous but misleading.

Dr. W. REES THOMAS said that the term moral imbecile was a legal and not a medical one, and while it might not be possible to diagnose such a condition, it was the doctor's business to fit into the term the cases it was meant to cover. Of 101 cases sent to Rampton in the last five years certified as moral imbeciles, about half were obviously feeble-minded and could have been certified as such; the majority of the others were cases of neurosis, psychoneurosis, and the like, with definite symptoms of which dementia præcox was the commonest. He regarded as the most important test the question whether the patient had any insight into his own condition.

Dr. F. C. SHRUBSALL considered that there was a type of case which fitted into the definition from the medical point of view but not from the legal point of view, because they had sufficient wisdom either not to come within the law or not to be found out.

### *Discussion.*

Mrs. PINSENT (who had been a member of the Royal Commission) said that the definition had been inserted because it was felt that general practitioners would not certify people who might show grave moral delinquency unless some such definition was included.

Dr. H. CORNER emphasised the point that a moral imbecile had no proper idea of the consequences of his action. The condition had been well described by a patient who said that he did foresee consequences, but that they appeared "dim, distant, and easily surmountable."

Dr. J. A. HADFIELD was sorry that so much of the discussion had centred on definition and so little on diagnosis. It was hard to differentiate between moral imbecility and ordinary psychoneurosis in people who might have developed early hidden complexes which emerged at a future time, commonly at puberty.

Dr. TREDGOLD, in replying, said that those with administrative experience did not deny the existence of moral imbecility, though admitting its rarity, and they were mostly agreed that the definition made it possible to get under care and control a type of case not certifiable as feeble-minded. The necessity of proving deficiency "from birth or an early age" stood in the way of certification; an early age should be taken to mean short of that age at which an adequate degree of mental development for managing the affairs of life is present

## BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on March 4th, Mr. H. J. WALKER, the President, in the chair, when Mr F E. FEILDEN read a paper on

### *Pyelography and its Value in Diagnosis.*

Pyelography was, he said, the introduction into the renal pelvis of a solution opaque to X rays; subsequently a radiogram was taken. The interpretation of the picture required care and experience. It might not always be possible to diagnose the pathological condition, but with experience it could be stated confidently that a given pyelogram represented a normal or a pathological condition. Frequently pyelography was the only means of arriving at a correct diagnosis, especially in some cases of painless hæmaturia. Pyelography suggested that many cases of so-called essential hæmaturia were in reality cases of congenital hydronephrosis associated with hæmaturia. It obviated the necessity of waiting until the patient was bleeding in order to discover from which kidney the hæmorrhage was coming, and was also particularly useful in the diagnosis of hydronephrosis before there had been much destruction of renal tissue and before the onset of infection.

In nephroptosis, continued Mr. Feilden, pyelography demonstrated the presence or absence of associated kinking of the ureter. The absence of kinking of the ureter in these cases raised a doubt whether operative interference was desirable. Lateral X rays, pyelograms, and, in difficult cases, lateral pyelograms were of assistance in distinguishing between the possible causes of shadows in the kidney. A uric acid calculus in the kidney could be demonstrated by the fact that after the solution was removed from the renal pelvis the shadow was accentuated by the staining of the stone. Normally the right pelvis was slightly lower than the left; if the left pelvis was lower than the right there was some pathological reason for it. If either lay below the third lumbar vertebra it was abnormal. Where a pyelogram could not be done owing to obstruction to the entrance of the solution, the resulting ureterogram might be of value. A dilated ureter from ureteritis suggested an infection of the kidney; a small ureter from disuse suggested a neoplasm. In suspected renal tuberculosis, unassociated with gross changes in urine, pyelography, by revealing a pathological condition of the kidney, would indicate the appropriate line of treatment. In malignant disease of the kidney pyelography revealed some change in the renal pelvis in a large proportion of cases. An early tumour of the renal capsule would not, however, be seen, and in this case a radiogram, after perirenal infiltration with oxygen, would be of value as an aid to diagnosis. It was important, said Mr. Feilden, to beware of underestimating the importance of the symptoms, "pain in the back" and "frequency." Either might be the patient's only complaint, yet his kidney might be the seat of gross pathological change. In cases of abdominal pain of obscure origin a pyelogram might be of the greatest assistance.

### *Discussion.*

The PRESIDENT referred to the disastrous results recorded in the early days of pyelography.—Mr. FEILDEN said that these results were due to inexperience and the use of silver salts, which were very irritating in the pelvis and calyces and produced focal necrosis.—Mr. J. R. H. TURTON asked whether a double pyelogram, without waiting a period of three weeks, was a safe procedure. It was most important not to mistake a calyx that had been cut across for a calculus.—Mr. FEILDEN said that to perform a bilateral pyelography was a perfectly safe procedure, if it was necessary to do it; it was especially helpful in differentiating between an early hydronephrosis and a normal but large renal pelvis. With experience a calyx (cut transversely) would not be mistaken for a calculus.—Mr. J. GRIFFITH referred to a case of hæmaturia in which the diagnosis could not be established until a pyelogram was done. This definitely showed a stricture at the junction of the pelvis and ureter and an open operation gave satisfactory results.—Dr. ST.G. B. D. GRAY asked the cause of the pain sometimes following pyelography.—Mr. FEILDEN said that it was very unusual for patients to complain of pain. Usually it was due to faulty technique. If the fluid was not removed from the pelvis spasm might be set up in the ureter. If there had been undue damage to the mucous membrane of the ureter the patient might have ureteric colic caused by blood-clot.—Mr. M. FITZMAURICE-KELLY inquired what solution was used, to which Mr. FEILDEN replied that he always used 15 per cent. sodium iodide as it gave an excellent shadow and was not irritating to any part of the urinary tract. He drew attention to the danger of doing pyelography in a case where a calculus was lodged in the pelvis at the junction of the ureter. It was necessary to make sure that the solution could be removed from the pelvis. Sometimes in these cases the calculus acted as a ball valve, that is to say, the solution could be introduced but not removed.

Following this discussion, Dr. NEVILLE COX showed a case of artificial pneumothorax illustrating the coin sound, and Dr. J. H. T. DAVIES showed cultures of different ringworm fungi.

## NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held on March 4th Mr. H. BELL TAWSE, the President, took the chair, and Dr. F. J. POYNTON (London) discussed

### *Some Abdominal Disorders in Childhood.*

Commenting on the longer intervals between feeds now in vogue for infants, he asked whether the fragile (though sound) child was not made over-hungry, with the result that it gulped its feeds and suffered from spasm and flatulence. In his experience this was what happened with delicate and ailing infants, though not with strong ones. Turning to the various kinds of food, Dr. Poynton dwelt upon the use of protein milk and foods not containing milk, speaking of their value in the difficult stage of acute gastro-enteritis and in chronic diarrhœa, when return to normal feeding had to be started. Giving his experience of hypertrophic stenosis of the pylorus, he described a series of 80 cases of his own, in which it was shown that a combination of prompt surgery, skilled nursing, and dieting had reduced the mortality from 70 to 6 per cent. He emphasised the importance of feeling the tumour. Discussing the dieting of cœliac disease, Dr. Poynton expressed the opinion that in some cases not only was fat not digested, but all the food elements were badly assimilated, and in addition the amount of food had to be much restricted.

*Acetonæmia was then considered*, and the two prominent features of the condition were illustrated —the nervous by examples of tram and train sickness, night terrors, and other evidences of nervous instability; the alimentary by the rare but clear-cut cases in which acetonæmia is diagnosed as the primary illness, but the actual cause is found to be volvulus of the small intestine. In classical cases of cyclic vomiting acetonuria might precede the vomiting, though in his experience this was exceptional. The evidence, he thought, pointed to some pre-acetone body as the essential poison. He concluded by showing drawings and radiograms of chronic intussusception.

The PRESIDENT, Dr. WILKIE SCOTT, Dr. J. A. BRIGGS, Dr. F. H. JACOB, Dr. R. G. HOGARTH, Dr. LANE, Dr. B. R. TRUMAN, Dr. C. H. ALLEN, Dr. W. T. ROWE, Dr. F. CROOKS, Dr. D. HUNTER, and Dr. JESSIE MORTON took part in the discussion.

## LIVERPOOL MEDICAL INSTITUTION.

AT a pathological meeting held on Feb. 25th Dr. J. C. M. GIVEN, the President, took the chair, and Dr. HOWELL EVANS read a paper on

### *Recent Advances in Knowledge of the Blood Platelets,*

with special reference to hæmorrhagic diseases and pathological thrombosis. Discussing the origin and specificity of the platelets, he mentioned especially the experimental work of Ledingham, Bedson, and Robertson, which, he said, afforded final proof that the platelets are separate blood elements. He then described the morphology of the platelets and a simple method of enumeration. Apart from their known function in connexion with blood coagulation, their importance in preserving capillary tone was important, capillary leaking and increased bleeding time being associated with deficiency. When the platelet count was very high, on the other hand, the capillaries seemed to be tightened up, and bleeding time was much diminished. Dr. Evans enumerated the phenomena associated with thrombocytopenia or platelet deficiency as follows: (1) slightly delayed coagulation time; (2) prolonged bleeding time; (3) failure of clot retraction; (4) diminished capillary resistance; (5) spontaneous capillary hæmorrhage. He showed that in a series of ten cases of primary and secondary purpura, with low platelet counts, the coagulation time, though usually stated to be normal, was in reality moderately delayed. The delay did not, however, approach the delay seen in hæmophilia, where the platelets were normal in numbers, but qualitatively abnormal. After classifying the causes of thrombocytopenia and discussing the primary disease, idiopathic purpura hæmorrhagica, Dr. Evans summarised the reported results of splenectomy for this condition and described two recent Liverpool cases in detail. Turning to conditions in which there was a rise in the platelet count, he pointed out that in certain of these conditions—namely, the convalescent period after infections such as typhoid and pneumonia, chlorosis, and certain forms of splenic anæmia—spontaneous thrombosis frequently occurred. In a series of six cases after splenectomy he had observed a definite shortening of coagulation time associated with high platelet counts. In one of these cases, a splenic anæmia of the Banti type, the platelet count persisted after splenectomy at a level of about 1,500,000 until the thirtieth day, when the patient died from mesenteric thrombosis. Similar fatalities after splenectomy in splenic anæmia associated with persistently high platelet counts had also been reported by Rosenthal. These facts showed a definite correlation between high platelet levels, shortened coagulation time, and clinical thrombosis, and emphasised the need for studying the platelet factor in its relation to all cases of pathological thrombosis.

# Reviews and Notices of Books.

## THORACIC SURGERY.

By HOWARD LILIENTHAL, M.D., F.A.C.S., Professor of Clinical Surgery, Cornell University. London and Philadelphia: W. B. Saunders Company. 1925. In two volumes. Pp. 1204. £4 10s.

IN no branch of surgery have greater advances been made in recent years than in the surgery of the thorax, and for those who have not followed its development these volumes will contain many surprises. The principles of ordinary surgery, which lead to certain victory in others parts of the body, may here lead to failure, since the conditions of success are entirely different. This treatise furnishes the substantial scientific foundations upon which the author and his colleagues have built up their unrivalled clinical experience. Prof. Graham contributes an important article on the physiology of the thorax, wherein he points out the differences between the conditions in thoracic and in abdominal surgery. He discusses at length the results of pneumothorax and the means by which damage to the mediastinum may be avoided; also the influence of a pneumothorax upon the opposite lung, the mechanism of compensation as to aeration and to circulation, and its effects, especially as regards exudation, both upon the compressed lung and upon the pleura. These considerations are at the root of modern lung surgery, and every worker will be grateful for such a clear account of a difficult subject. Roentgenology is treated by Jaches in an article remarkable for the excellence of the photographs of actual cases which illustrate it. These give a clear idea of what should be looked for in a good X ray, and indicate the important part played by this method of examination in thoracic work. An equally valuable article deals with anæsthesia and shows the elaborate precautions which must be taken, and the special knowledge and skill which are required, if success is to be achieved.

In the main section of the work Prof. Lilienthal deals lucidly with a vast number of conditions. He gives considerable space to the discussion of subjects which have not yet emerged from the experimental stage, such as the surgery of the valves of the heart, but he wisely devotes most of his book to the really practical problems which surgeons have to face. From a series of informative articles it is invidious to select any for special praise, but those on empyema, on suppuration in the lung, and on tuberculosis are outstanding. The section on empyema disposes once for all of the old-fashioned notion that empyema can be adequately dealt with by the house physician, whilst that on tuberculosis opens up a new field whose extent and possibilities cannot be foretold.

Without pretending to the encyclopædic proportions of Sauerbruch's great treatise, these volumes succeed in presenting a convincing account of the subject in an accessible and attractive form.

## FRACTURES IN GENERAL PRACTICE.

*Die Behandlung der Knochenbrüche durch den praktischen Arzt.* Von Geh. Hof. Prof. Dr. FRITZ LANGE. München: J. F. Lehmann. 1926. With 81 figures. Pp. 124. M 3 50.

PROF. LANGE, in his preface, says that his book is not intended for orthopædic surgeons. His aim is to put before the general practitioner the methods of after-treatment employed in orthopædic hospitals after osteotomies which are sometimes multiple, leaving the limb a mere chain of bones, a proceeding first carried out by the late Sir William Macewen. Prof. Lange gives reasons for confining his instruction to treatment by means of extension and gypsum and in some cases splints. He much prefers the zinc-glue bandage to other adhesive materials for the application of extension.

All the typical fractures are considered in systematic manner, and the method of treatment is described which the author finds best for each. In general he relies greatly upon a combination of end-traction with lateral corrective pressure by pads attached to, but not under, a plaster-of-Paris splint, which latter serves as a fixed point and affords counter-pressure. These principles he applies alike in fractures of the neck of the femur and in those of the ankle or the upper extremity. His advice as to the treatment of fracture of the neck of the femur in old people appears to be sound and is the outcome of great experience, but we can hardly suppose that he expects the general practitioner, for whom his advice is ostensibly intended, to carry out the bone-grafting or pegging operations which he describes for ununited fractures in this region. The author's sole reference to the Thomas splint, which he admits played so great a part in reducing the mortality from gunshot fracture of the femur among the British in the late war, is to be found in a paragraph in which he gives the entire credit for its introduction and for the consequently enormously diminished mortality to the Americans, entirely ignoring the work of all British surgeons. It is hardly necessary to remark that the improvement was effected before the American forces landed in France Naturally, perhaps, he prefers for such cases his own pattern of field splint, of which he gives an illustration and a full description. The results with this were no doubt excellent, but it lacks the simplicity and portability of the Thomas knee splint.

This little book is well printed and the figures are clear

## MODERN MEDICINE.

Third edition. By the late Sir WILLIAM OSLER. Re-edited by THOMAS MCCRAE, M.D., F.R.C.P. Lond., Professor of Medicine in the Jefferson Medical College, Philadelphia; assisted by ELMER H. FUNK, M.D. Vol. II. London: Henry Kimpton. 1926. Pp. 891. Set of six volumes, £13 12s.

AN extended and comprehensive work on medicine is in these days not an academic luxury to the occasional reader, but a bare necessity to every practitioner who attempts to base his work on current knowledge, and must be constantly kept up to date. In this way it is possible for him, on the one hand, to bring his practice up to the highest modern level, and on the other, to keep clear of those innovations which, after their little day, are found wanting in all but imagination

Twenty-eight authoritative physicians have contributed to this volume. Sir William Osler's weighty article on Syphilis is typical, in its lucidity and method, of his attractive writing, Dr J. W. Churchman assisting in the section, which has been revised by Dr. L. A. Conner. Particular attention is paid to the diagnosis in the febrile stage and to the mucous and cutaneous lesions. Dr. F. J. Poynton has been most successful in treating rheumatic fever in a similar fashion—i.e., as a national disease requiring organised treatment—and has summarised the methods of prophylaxis of the heart disease of childhood on the American pattern. It is interesting to note that the section still stands in the part of the volume devoted to diseases of unknown or doubtful ætiology. In this part also is an excellent article, well illustrated, on Small pox, by Dr. E J. Beardsley; the historical side of this subject as well as that of Vaccination (by Dr. G. Dock) is dealt with fully; the sections on Measles and other Exanthems are written by Dr. John Ruhräh. Dr. Thomas McCrae, who re-edits the book, contributes a section on Typhus Fever, in which he emphasises the occurrence of mild and often unrecognised forms of the disease in sporadic form. Dengue is dealt with by Dr. T. G. Coleman and Rabies by Dr. M. P. Ravenel, the human and canine forms of the last-named disease are well described, and the effects and method of the Pasteur immunisation summarised.

The second part of the volume is concerned with the Protozoan Infections. Dr. R. P. Strong, writing on

Amœbic Dysentery, devotes much space to classification of different amœbæ occurring in man and describes inoculation experiments; the pathology is well illustrated, and treatment by emetine and its variants described in careful detail. Malarial Fevers are exhaustively dealt with by Dr. Charles Craig, and his methods of General and Personal Prophylaxis should be known by all practitioners in temperate climates. Dr. J. W. Stephens, writing on Blackwater Fever, states that statistics give a definite verdict against the use of quinine therapy in this condition, of which the ætiology is still obscure. Sir David Bruce and Dr. G. Low combine in the section on Trypanosomiasis, in which we learn of the improving prognosis in this very fatal disease under modern methods of treatment. The Leishmaniases are described by Dr. B. C. Crowell, with illustrations of the development of the Leishman-Donovan bodies.

In Part III. the Spirochætal Infections are discussed. The article on Syphilis has already been referred to. Dr. Conner writes on Yaws, Dr. John Todd on Relapsing Fever, and Dr. McCrae has revised the article by the late Dr. James Carroll on Yellow Fever. Finally, Dr. E. Funk contributes a chapter on Spirochætal Jaundice and Rat-bite Fever. Part IV. is devoted to the Diseases caused by Animal Parasites, a section written by Dr. C. W. Stiles and prefaced by a useful general discussion and a classification of the parasites and their nomenclature. Part V., by Dr. Funk, deals with diseases due to physical agents. Chemical and organic poisons are the subject of Part VI., to which Dr. Norman Gwyn contributes two chapters; in an important section on Lead he describes the occupational incidence of chronic poisoning and the regulations in force to prevent it. The danger of a high calcium value in the diet is shown to be a storage of lead in the bones, which an upset of metabolism may cause to be liberated with disastrous results at a later date. The chapter on Alcohol, Morphine, and other Poisons, by Dr. Alexander Lambert, is full of interest and will be found an excellent guide to anyone having a case of alcoholic or other poisoning to deal with. The psychological cause of alcoholism in general is emphasised, and the consequent importance of dealing with the particular psychosis in a given case is pointed out. The treatment by belladonna of both morphinism and alcoholism is recommended and described in detail. A chapter on Food Poisoning is contributed by Dr. E. C. Dickson. Deficiency Disease forms the subject of the last part of the volume, in which chapters on Pellagra (Dr. E. J. Wood), Beri-beri (Dr. W. E. Musgrave and Dr. Crowell), Scurvy (Dr. R. Hutchison), and Rickets (Dr. G. Still) are included.

Altogether this volume contains many wise and valuable articles, and the appearance of the next will be anticipated with interest.

### PEPTONE IN BRONCHIAL ASTHMA.

*The Treatment of Bronchial Asthma by Intravenous Injections of Peptone.* By P. BOOT, M.D. Amsterdam. Amsterdam: H. J. Paris. 1925. Pp. 135. Fl.3.25.

Dr. Boot observes a series of cases of patients suffering from bronchial asthma in the clinics of the Binnengasthuis in Amsterdam. Of the 20 patients described, 11 more or less improved under the injection of peptone. In four cases high doses have shown improvement, whereas small quantities have failed. In one case there was hypersensibility for peptone. In one case peptone did not have any success, but tuberculin caused improvement. In the rest of the cases no result was obtained, except in one case where an auto-vaccine benefited. The author comes to the conclusion that the peptone suppresses the asthma and states his agreement with Dr. Auld[1] that the intervals of the recurrence of the attacks become less frequent after the peptone therapy. In the 20 cases which Dr. Boot describes, the method has generally been as follows. He starts with 5 per cent. of Armour's Peptone No. 2, beginning with ½ c.cm. and going up to 3 to 4 c.cm. In each case the blood was examined and skin reaction done. Although elaborate tables have been prepared and bacteriological methods and vaccine therapy are described, the clinical aspect should have been more elaborately dealt with for the treatment to be of use to the general practitioner. The reader, although finding interesting and well worked-out points, still obtains very little evidence of successful results. But the careful investigation displayed should be of help.

### THE MUSCULAR SYSTEM.

Second edition. By HAROLD BURROWS, C.B.E., M.B., F.R.C.S. London: The Scientific Press. 1926. Pp. 184. 1*s.* 6*d.*

THIS little book gives an excellent account of the various muscles of the body, grouped according to their actions. It is plainly intended for practical use by the clinician, and in this edition a useful chapter has been added dealing with the localisation of nerve lesions by means of muscle tests. The volume includes many useful illustrations, and is an example of wonderful value for price. We commend it to the notice of art students.

### ANNALS OF MEDICAL HISTORY.

December, 1925. New York: Paul B. Hoeber. Pp. 319–445 and Index. $2.50.

THE contents of this number, which completes the 1925 volume, range in point of time from Gilles de Corbeil of the twelfth century to Mark Twain of the nineteenth. Dr. E. E. Hume contributes an interesting paper upon Pettenkofer and his theory of the ætiology of cholera and other intestinal diseases, a theory now known to be erroneous, but even the mistakes of great minds are instructive. Pettenkofer, of course, won his fame as a chemist and physiologist and not as a pathologist. Dr. R. T. Williamson writes upon Corrigan and his career. Corrigan was one of the greatest of the many great Irish physicians who flourished during the first half of the nineteenth century and his name is known to every medical student by the expression "Corrigan's water-hammer pulse," indicative of aortic regurgitation, a condition the extreme importance of which he was at least the first to recognise, if not the first to describe, for that honour belongs to Hodgkin. The article is given additional value by an admirable photographic reproduction of the portrait of Corrigan in the Royal College of Physicians in Dublin. Dr. Stephen D'Irsay takes for his subject the life and works of that too little known but singularly interesting leech, Gilles de Corbeil, 1180–1223, physician to Philip Augustus. This is a very good paper with a copious bibliography. Here and there Dr. D'Irsay is obscure—for instance, in the following sentence: "The works of Gilles de Corbeil were all clad in poetic form. That form was the Leonine verse; pure hexameters interspersed with distichs." It is true that Gilles did use Leonine verses occasionally, more especially in the Hierapigra—e.g., Hierapigra VIII., vv. 63–68—but they are by no means the rule, even in that poem; in the other poems they are rare, and why the Leonine verse should be described as "pure hexameters interspersed with distichs" we cannot understand.

Dr. F. R. Menne writes about Rokitansky and his admirable work in pathology, and Dr. Aitchison Robertson has gathered together various delightful extracts from old writers for and against the Powder of Sympathy. Mrs. Taylor contributes the final portion of her most interesting reminiscences of her father, Crawford Long; and Dr. L. J. Bragman discourses upon the medical wisdom of Mark Twain as shown in his writings. The group of original papers ends worthily with a charming little poem by Theodor Storm, being an address to an ophthalmic surgeon from his grateful patients, here recorded by Dr. F. H. Garrison.

A Necessity
in
The Hospital
The Nursing Home
The Sick Room

by BURDETT, though modified in different directions by altering circumstances from that originally devised for the Metropolitan Hospital Sunday Fund, was subsequently elaborated for use by King Edward's Fund, and has now developed into a revised and uniform system, such as is held by the Voluntary Hospitals Commission as essential to accurate statements, whether general or relative. Further, the annual reports issued by the joint council of the British Red Cross and Order of St. John, edited first by the late Sir NAPIER BURNETT and subsequently by Dr KAY MENZIES, provide invaluable statistics summarising the situation in some 600 hospitals from year to year, and in these reports the totals emerge with their significant information, more than which can hardly be expected. Further, we note in Mr. BROCK's paper a passage commending the efforts of the local hospitals committee at Manchester, where hospital statistics are more complete than in any other city outside London, and we echo his hope that Manchester's example will be followed in other great cities. It is clear from all this that need for financial order in these great charities is now being widely appreciated.

The following vitally important questions are set out by Mr BROCK as requiring answers, if hospital statistics are to be of proper use to the community in general: (1) Is the public doing its duty to the hospitals? (2) Are the hospitals solvent judged by ordinary business standards? (3) If they are not solvent, in what directions can expenditure be reduced or income increased?' It will be seen that the fundamental assumption is made that the public has a duty to the hospitals, and we need not recapitulate the grounds on which it is made. But the running of a voluntary hospital must to-day be seen by all to be a business proposition, for the neglect of curable sickness results in terrible waste of man-power and money. At the same time the hospital provides a centre for the promotion of medical research and for the education of medical men, both of which activities can be supported on purely business grounds, for if it did not fall naturally to the hospitals to make such provisions the community would have to be taxed heavily in order to obtain them elsehow. If the second
question cannot be answered in the affirmative the
rst must be answered in the negative, for the public
not doing its duty if the hospitals remain insolvent.
his brings us to the third question how, in case the
spitals are not solvent, can they be made so?
duction of expenditure, or increase of income, or
th, must cover any possible reply which leaves
ation out of question. The fact that the administra-
of all the hospitals in Manchester has resulted in a
per bed at the various institutions which compares
urably with the cost at similar hospitals elsewhere,
s that possibilities of economy lie in sound
isation and in intelligent methods of regrouping;
who have studied the question at large will agree
Mr. BROCK's view that we must expect the
l solvency in the voluntary hospitals to come
from increase of income than from diminution
nditure. And here the outlook is fair. The
ls are essentially voluntary and, therefore,
s' payments cannot be indefinitely increased,
rkmen's contributions, especially in the big
al centres of the North, now represent a
tial and assured source of income; and while,
extent, these contributions fall under the
y of patients' payments, it is only in a modified
at they can be so regarded. The true view of
ayments would hold them as mass subscriptions;
ro given not with the idea of the individual
of a patient, but with the intent to support

a great organisation which can only discharge its beneficent responsibilities if it is supplied with the material means. The appeal for workmen's contributions differs in no respect from the appeal to individual donors; it is founded on exactly the same principles, and as such is appreciated by the workman and has met with steady support.

Annual subscriptions to voluntary hospitals come in the main from the middle classes, directly as well as indirectly through the great Funds. This is a point that should be remembered in connexion with the fact that these are the classes who, in existing circumstances, derive the least direct benefit from the institutions. But, handsome as their support is, there is no doubt it would be substantially increased if organisations for securing subscriptions were more thorough. Individual charities canvass vigorously, with the result that institutions do not always receive endowments proportional to their deserts; but at best this way of wringing money out of the public is costly and capricious, and it is not surprising that Mr. Brock should say that the money obtained does not represent in some cases what might fairly be expected from a particular community. He brings forward the example of Leicester where the collection of hospital subscriptions is conducted on plan. At Leicester practically all occupiers of houses above a certain rateable value are visited and asked for at least a minimum subscription, and the inhabitants can hardly escape from the obligation to assist the Royal Infirmary and other institutions. But they enjoy in return immunity from an endless series of competing appeals and the satisfaction of knowing that contributions are going in the right direction. There is no doubt that in a similar way much money could be regularly obtained at other centres, but the question of paying wards ought to enter into our calculations at this point. To expect an increased revenue from workmen's contributions can be justified by the improvement in the economic position of a large section of what used to be considered the proper hospital population, but the middle classes, whose financial position is far less sound than it was before the war, can no longer be left aside to pay and never to receive. They subscribe to hospitals to which they do not go, and they are unable to command through consultants and specialists and institutional amenities the best treatment for their condition. The construction of paying wards would be a powerful incentive to many who do not as yet subscribe to the voluntary hospitals, and the due conditions for their provision are being arrived at gradually. There are problems here of different sorts, to which we have referred recently, whose solution should precede any general establishment of paying wards in connexion with voluntary hospitals; at the same time the needs of the middle classes will have to be met, and this is recognised by their medical advisers as well as by themselves. The provision of paying wards in connexion with existing hospitals should, we think, be regarded only as a temporary solution of the difficulties, but it is one that could come into existence promptly.

◆

## THE FUNCTIONS OF THE SPLEEN.

REMOVAL of the spleen does not produce any very disastrous results. The animal may be rather anæmic, it may have a diminished capacity of producing antibodies, it will be less resistant to enteric infection and more resistant to tuberculosis, it may be jaundiced less readily by hæmolytic poisons, it may perhaps develop a voracious appetite; and a good many other things may happen according to some observers, while according to others they may not. In any case, no change regularly follows splenectomy which has any great influence on the vitality or morbidity of experimental animals. It does not follow that man is equally indifferent; his standard is higher and he is more carefully observed, and in much larger numbers. But there must be a good many spleenless individuals in the world, and no definite asplenic syndrome has been identified as an illness. As an article of faith we must believe that if the spleen did nothing, it would not be there. In other words, the spleen is useful but not necessary. What is known of its functions is summarised by Dr. E. B. Krumbhaar in the last number of *Physiological Reviews* (1926, vi., 160), and his copious bibliography will enable anyone to follow the ramifications of any of the hypotheses or results of observation.

Last week we were able to publish some of the most recent progress which has been made by Prof. Joseph Barcroft and his colleagues at Cambridge. His lecture at Leeds is a supplement to one which he gave at Manchester some year ago, published in THE LANCET at the time (1925, i., 319). He deals with two main functions—the spleen as a reservoir of blood and its action in altering the resistance of red blood corpuscles. By fixing metal clips round the edges of the organ and X raying the animals, or by watching it through a celluloid window in the abdominal wall, Prof. Barcroft establishes that the spleen in a normal animal at rest is a good deal —two to perhaps four times—bigger than it is after death, and that our ordinary ideas of its actual size in vivo are by this amount in error. The excess of the living over the dead size is blood or red corpuscles, or something between the two. Hæmorrhage stimulates the spleen to expel this excess into the circulatory blood and the amount expelled is roughly proportional to the severity of the hæmorrhage. Exercise has a similar effect, and the possibility of adding fresh hæmoglobin to the circulating blood may help an animal to withstand CO poisoning. The spleen, therefore, functions as a reservoir of spare blood which can be emptied into the general circulation when desirable. Quantitatively it is not a large tank. The dead weight of the human spleen is about 0·25 per cent. of the body-weight, its live weight one supposes may be 0·75 per cent.; it can, therefore, add 0·5 per cent. to the blood which constitutes some 5 per cent. of the body-weight. Making allowance for the fact that the mixture discharged from the spleen is more concentrated than blood, we may conclude that the reservoir is able to increase the circulating red corpuscles by some 12 or 15 per cent. —a useful thing to do, but not necessary to life, though it may well be just enough sometimes to turn the scale in favour of survival. As Gross has shown, the human spleen goes through a regular series of age changes which leave it a fibrous and apparently rather functionless organ in middle life and later, and this is, perhaps, one of the explanations of its characteristic failure to achieve useful but unnecessary activities involved by age. On this and other points Prof. Barcroft will awaken attention, and he has enabled us to look at the spleen and its vagaries in the postmortem room with new ideas of interpretation in our minds. And if Henry Gray had not died of small-pox at the age of 34 he might have secured that his essay "On the Structure and Use of the Spleen," which won the Astley Cooper prize in 1853, should be as familiar as the "Descriptive and Surgical Anatomy" of 1858. We should, then, as Prof. Barcroft points out, have known the essentials of all this without being told, for Gray clearly states the main point and, indeed, might with a good deal of luck have just been able to rise in Prof. BARCROFT's audience and state it again.

The other topic with which Prof. BARCROFT dealt in his recent lecture is the resistance of red cells to hypotonic saline. The red cells coming out of the spleen are less resistant than those going in; if the spleen is made to empty itself out by stimulating the splanchnic, the red cells which come in as it is allowed to refill acquire their increased fragility almost at once. What this means we do not know. Especially we need to find out how much blood passes through the spleen per hour, whether any red cell goes into the spleen more than once, and hence whether this acquired fragility is lost again in the general circulation. But we can add to these facts the human experience that splenectomy alleviates congenital acholuric jaundice and raises the resistance of the fragile red cells which are characteristic of that disease, and that it cures splenic anæmia. Perhaps we have at last an explanation of the puzzling variety, described by Prof. E. H. KETTLE and others, of the anatomical changes in the large spleens removed so successfully in this condition; any hypertrophy of the splenic tissue may diminish the resistance of so many cells or diminish it so much that actual anæmia results irrespective of the original cause of the splenic enlargement. Add, too, that splenectomy inhibits the production of jaundice by arseniuretted hydrogen and of anæmia by phenylhydrazine and perhaps also, in view of the possible relationship between red cells and blood platelets, that it can cure purpura. All of which adds up to the summary conclusion that the spleen does something to red cells which makes them more easily destroyed. Whether this mechanism is one of emergency or in constant use remains to be discovered. The spleen is no doubt sometimes useful; it is evidently not necessary; medicine supplies us with illustrations of how it may be harmful.

◆

## INFECTIOUS DISEASE LEGISLATION.

WHAT is the legal meaning of "infectious disease"? The expression occurs in the Public Health Act of 1875—for example, in Sections 80 (by-laws as to common lodging-houses) and 120 (cleansing and disinfection of premises and articles)—but it is not explained. In Section 123 of the same Act (relating to conveyance of infected persons) we are introduced to another unexplained expression, "infectious disorder", while in several other sections—for instance, 121 (destruction of bedding) and 124 to 129 (removal to hospital, penalty on exposure, &c.)—there is a further variety, "dangerous infectious disorder," no guide being furnished as to its application. Elsewhere in the Act we find allusions to "cholera or any other epidemic, endemic, or infectious disease," with a subsequent variant "any formidable epidemic, endemic, or infectious disease." Where a term like "dangerous infectious disorder" enters into the by-laws of local authorities, some degree of uniformity may be obtained by the adoption of a standardised definition from model by-laws drafted in Whitehall. And probably there is in practice but little doubt whether a particular disease comes within any of these several statutory classifications or not. Nevertheless, the vagueness of the phrases and the deliberate adoption by Parliament of different expressions and of strengthening epithets like "dangerous" and "formidable" might at any time present the law courts with puzzles for solution. The Infectious Disease (Notification) Act of 1889 was much more explicit. As is well known, Section 6 of that statute specifies the "infectious disease to which this Act applies." The list consists of small-pox, cholera, diphtheria, membranous croup, erysipelas, scarlatina or scarlet fever, and typhus, typhoid, enteric, relapsing, continued, or puerperal fevers. Additions can be made to the list locally on the resolution of the local authority with the approval of Whitehall. This list is definite enough, and it has been made to do duty for other purposes. It is adopted by the Infectious Disease (Prevention) Act of 1890 (which contains a similar provision for local extensions), the Public Health (London) Act of 1891, the Isolation Hospitals Act of 1893, and the Public Health Acts Amendment Act of 1907. Last year it was further applied, the specified "infectious diseases" in the 1889 Act being deemed "dangerous infectious diseases" within the meaning of certain provisions of the Public Health Act of 1925—i.e., the non-adoptive provisions of Sections 57 (contact with dead body) and 58 (common lodging-houses); at the same time the Minister of Health was authorised by Parliament to enlarge this list of "dangerous infectious diseases" by orders either general or local.

From this survey of the field it will be seen that the weapons we possess for fighting infectious disease under the various Public Health Acts are of two kinds. On the one hand, there are powers which are available against the specific diseases mentioned in the 1889 list (with any local extensions); on the other hand, there are powers for use generally against unnamed diseases. This situation gives rise to anomalies to which Dr. T. S. MCINTOSH[1] has usefully drawn attention. Thus, plague was made notifiable under departmental order in 1900, and was dealt with by three sets of regulations in 1907 in relation to ships from foreign ports, coasting vessels, and ships outward bound. But plague is not mentioned in the list in the 1889 Act; it is, therefore, not within the 1890 Act, unless by virtue of local application; consequently, the power of disinfecting bedding under the 1890 Act will not apply to the flea-infested mattress on which a plague patient has been sleeping. Again, dysentery is notifiable by virtue of the Ministry of Health Regulations of 1919, but, as a matter of general law, it is not an infectious disease within the 1907 Act, so that anyone knowingly suffering therefrom is not universally prohibited under Section 62 of the 1907 Act from carrying on business and spreading the risk of infection. No doubt these anomalies are mitigated by the elastic system of departmental orders and regulations which substantially cover the field; but its very elasticity has the drawback that practitioners are not always aware of the latest developments. The list of diseases made notifiable in England under departmental regulations is an ever-lengthening one; the regulations usually apply to the Infectious Disease (Notification) Act of 1889 and other enactments, but the language is by no means uniform. The list does not include infective jaundice and infantile paralysis, which are both notifiable in Scotland; it no longer includes measles and German measles, which were added in 1915 but were removed after the war, though often made notifiable locally; and it does not include venereal disease, concerning which we recently noted the interesting local provision in Section 68 of the Bradford Corporation Act of 1925. But the list does include (as from the years mentioned in each case) plague (1900), tuberculosis and except in London (where they are notifiable under L.C.C. order of the same year) cerebro-spinal fever and acute poliomyelitis (1912), ophthalmia neonatorum (1914), acute encephalitis lethargica and acute polio-encephalitis (1918, made permanent in 1919), and malaria, dysentery and trench fever, acute primary pneumonia and acute influenzal pneumonia (1919). Is every practitioner, one wonders, aware that acute primary pneumonia is a notifiable disease? When Parliament undertakes the revision and consolidation of public health legislation, there will be an opportunity to make all the weapons in the public health armoury available against all infectious diseases even though those weapons may be more effective and appropriate in some cases than in others.

# Annotations.

"Ne quid nimis."

## THE BIOCHEMICAL SOCIETY.

THE Biochemical Society held its hundredth scientific meeting at University College, London, on Saturday last. Although celebrating a century, the Society is still in its teens, for it originated in January, 1911, at the instance of Mr. J. A. Gardner and Prof. R. H. A. Plimmer. Moved by an announcement that an alien was to be invited to teach British workers how to apply chemistry to biological problems, these two biochemists had a conversation on the telephone which resulted in the despatch of 55 postcards to their countrymen already engaged in this field of work. A meeting resulted at which the 32 attenders determined to form a society, as they put it, "to promote intercourse among those biologists and chemists mutually interested and concerned in the investigation of problems common to biologists and chemists." From this small beginning, in spite of national and international upheaval, the Society has grown to a present membership of 485, of which one-tenth is in the British Dominions overseas. At a dinner held on the evening of March 13th to celebrate the occasion Sir F. Gowland Hopkins presided, and the salient facts in the history of the Society were related by Mr. Gardner and Prof. Plimmer, respectively treasurer and first secretary of the Society, and by Prof. A. Harden, editor of the *Biochemical Journal.* The debt owing to these pioneers in surmounting early difficulties was duly honoured by those present. Realising the importance of adequate publication, the original officers of the Society and their associates acquired the *Biochemical Journal*, at that time the property of the late Prof. Benjamin Moore, and were fortunate in securing as co-editors the services of the late Sir William Bayliss and of Prof. Harden. A circulation of about 500 copies was at first the distant aim, but we learn that the number distributed now more than doubles this figure. The Society takes some pride in the fact that in spite of such heavy commitments its annual subscription remains below that of any similar society. The dinner concluded with an eloquent tribute paid by Prof. E. H. Starling, who took the chair at the scientific meeting, to Sir F. G. Hopkins's leadership. Hopkins had, he said, excited the respect of fellow-scientists for a new branch of chemistry and was himself the founder of a great biochemical school at Cambridge. It remains to note that, among the papers read at the hundredth meeting, was a brilliant research on the chemistry of thyroxin by Dr. C. R. Harington. There is no doubt that a Society started with such happy augury, and showing in its adolescence such signs of active growth, has yet further conquests to make.

## THE CHANCELLOR AND THE INSURANCE SURPLUSES.

THE existence of continued large surpluses in the National Health Insurance Scheme has, as we anticipated, led the Chancellor of the Exchequer to seek some relief for the taxpayer by reducing the Exchequer contribution towards the cost of benefits under the scheme. The Economy Bill, with its explanatory memorandum, proposes that the Exchequer contribution, instead of being as at present two-ninths of the cost of benefits of men and women, should for the future be one-seventh in the case of men and one-fifth in the case of women. In the interpretation of fractions we confess to a sympathy with the writer—we think it was Mr. A. A. Milne—who said that when the price of his shares one day moved from $10\frac{5}{8}$ to $10\frac{11}{16}$ it was a moot point whether they had, in fact, gone up or down. It becomes clear, on reading further into the memorandum, that in this case the movement of the Exchequer fraction is a downward movement, and the Exchequer, we are given to understand, will contribute in future £2,800,000 less to the cost of benefits than it would have done under existing arrangements. The Royal Commission, in their report, found that, on a modification of the original actuarial calculations in connexion with national health insurance, it had become established that more money was being raised than was required to pay for the normal benefits. The Exchequer has now absorbed the available margin, so that no part of it can be applied to extensions of benefit. The cost of the extensions which the Commission has recommended and placed first in order of priority—the provision of specialist services, bedside consultations, and laboratory aids—can only be met, in the view of the Commission, by pooling one-half of the future surpluses of societies, which will be considerably diminished by the withdrawal under the Economy Bill of part of the Exchequer contribution. We may expect to hear something on this subject in the near future from the approved societies. It is true that the money has accumulated owing to the amount of actual sickness being less than was allowed for by the actuaries who drew up the scheme in the first instance, but the surplus has been allotted in part, and was to be allotted in far larger measure, to relieve the minor forms of ill-health which, although they do not amount to scheduled illness, actually sap the health of the nation. Any reduction of the Exchequer grant, although its effect may not be immediately felt, will limit the possibility of instituting dental and nursing services which are as essential to the insurance scheme as other benefits, and it would be lamentable if at the moment when the report of the Royal Commission has opened the eyes of many people to the more hopeful developments of health insurance the opportunity should be lost. Rapacity is a necessary quality in a Chancellor of the Exchequer, but immediate economy is to be deplored when consequent waste in the future must result.

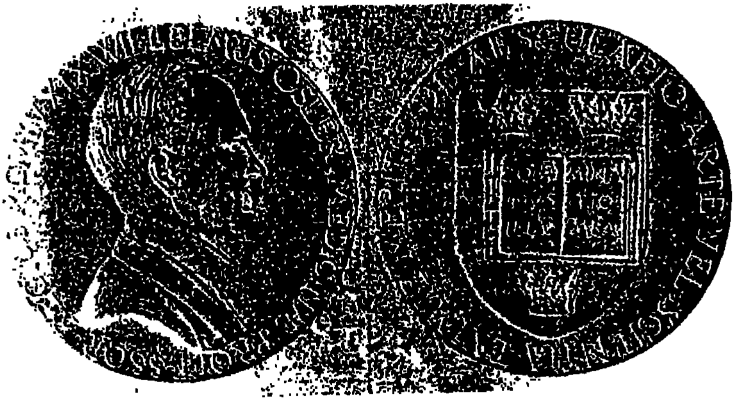
## MALARIA PROPHYLAXIS IN THE ROMAN CAMPAGNA.

THE protection of 800 square miles of Roman Campagna against malaria suffered a set-back during the war, when quinine became expensive, when the young doctors who had learned to treat cases and see to quinine distribution were taken away for the army, as were the nurses who helped in prophylaxis, and when drainage schemes were stopped. Later, to grow the wheat the nation wanted, young workers, who knew nothing of quinine, were brought in, and Austrian prisoners who suspected quinine when offered. These refused to take it and suffered severely. Where enough was available and quinine was given in sufficient doses malarial prophylaxis by quinine justified itself, though it was much spoken against by people who complained that it had brought back malaria to the Campagna. This greatly vexed Signora Celli-Fräntzel, who saw the life-work of her husband, Angelo Celli, being discredited, and, finding she could make no headway by articles or lectures, she took service as a Red Cross nurse at Maccarese, one of the worst spots in the Campagna. Here, taking 10 gr. of quinine a day herself, she set out to win the peasants back to the true faith, as she tells in the December number of the *Archiv für Schiffs- u. Tropen-Hygiene*. The peasants were ready enough to take quinine from her if they were ill, but avoided prophylaxis until one pernicious case died in 24 hours. Then some allowed themselves to be persuaded, and in a little, two-thirds were taking quinine. Finally, she converted even Prof. Grassi, hitherto unconvinced, on whose advice the King put her in charge of malaria prevention on one of his large estates. The next year the Ministry of Health gave her eight nurses, who visited the farms and saw the tablets swallowed. In three years at her centre 807 protected persons had 24 (3 per cent.) attacks, but 102 unprotected had 31 (30 per cent.); for the rest the attacks of the protected were trifling, none was pernicious. Quinine prophylaxis requires, says Signora Celli, zeal, determination, and personal attention. The Italian Marine Corps controlled administration by urine examination. The Italian Artillery was notably free from malaria owing to the closeness with which men and officers were thrown together and the interest taken by the officers in seeing that their men took their little daily dose.

## THE OSLER MEDAL.

THE photograph which we publish shows the obverse and reverse of the bronze medal which has been designed for the Committee of the Osler Memorial Fund by Mr. F. Bowcher. The Osler Memorial Fund was accepted by the University of Oxford last year together with a plaque by Mr. Vernon, of Paris. An account of the unveiling of the plaque by the Vice-Chancellor in the University museum on June 10th, 1925, was published in THE LANCET.

THE OSLER MEDAL: OBVERSE AND REVERSE.



The Osler memorial bronze medal is to be awarded once in every five years to the Oxford medical graduate who shall, in the opinion of the Board of Awarders, have made the most valuable contribution to the science, art, or literature of medicine, and who has not previously received the medal. The residue of the income of the fund, after payment of all expenses in connexion with the medal, may be used at the discretion of the members of the Board of Awarders resident in Oxford, in making grants from time to time to teachers in the Oxford Medical School, to enable them to pursue some special study connected with medicine outside the University. The first award of the medal was made on June 10th, 1925; the next will therefore be made in 1930.

## MENSTRUATION AND PAIN.

WHEN the Victorian young lady took to her room and left word that she was "unwell," she was not taking refuge in an empty euphemism. The monthly periods seem to have been a much more severe ordeal to her than they are to her grand-daughters, and she accepted malaise, headache, and more or less severe pain in the hypogastrium and back as part of the order of Nature. It is true that some gynæcologists still teach that pain is the normal accompaniment of menstruation, but statistics show that only about 70 per cent. of healthy modern women, such as public school girls and Civil Service candidates, experience it; and certainly if women suffered as a sex what they are supposed to have suffered 50 years ago they could not have taken the large part they have in business and professional life. Nevertheless a fair number still find their periods a real handicap, and their sufferings have provoked the question, "Why does a normal function cause pain?" The first reply is, of course, the counter-question, "Is it a normal function?" Prof. A. Pinard and others have maintained that the normal woman would never menstruate; Nature intended that from her first period onwards her sexual life should be a continuous series of pregnancies and lactations. The subject is discussed fully and with an exhaustive bibliography in the able monograph which Prof. V. Wallich has written for Prof. Ch. Richet's monumental "*Dictionnaire de la Physiologie*," now in the press. This monograph has been printed and circulated separately, from the dictionary's formes.[1]

Prof. Wallich points out that although the hæmorrhage has naturally drawn both social and scientific attention to itself, to understand the real significance of the monthly cycle it is essential to follow its variations through the whole mammalian species and to study the complex of symptoms, of which bleeding is only one and not an invariable one at that. The main fact is a periodical congestion of the female genital organs which marks the crest of their rhythmical activity and ceases when they take up their proper work of reproduction. Anatomical observation shows a profound modification of the mucosa uterina, the whole of which undergoes tumefaction and hyperplasia in order to fit it to receive and nourish the fertilised ovum. Simultaneously there is a psychic awakening that induces the female to seek the company of the male. This phenomenon of congestion occurs in all mammals and is more intense in some than in others; there is always some degree of hæmorrhage, but this may take place only in the interstices and may never show itself in the uterine cavity or at the vulva at all. Prof. Wallich states that the bleeding is probably more profuse in the higher primates because their heavily-muscled and plexiform uterine wall locks the capillaries of the mucosa and prevents them from expanding properly at the time of congestion. They are fragile and rupture easily. In the horned uteri of the lower mammals the vessels have a bed of cellular tissue in which to expand, and any hæmorrhage there may take the simple form of infiltration into the submucous layer.

---

[1] Librairie Félix Alcan, Paris.

It has been demonstrated beyond question that menstruation depends on ovarian function. It ceases altogether when the ovaries are removed, but the slightest trace of ovarian tissue left behind or ingrafted will cause the phenomenon to persist or return. Prof. Wallich concludes that every part of the ovary is concerned in producing the reaction and that no one part preponderates over the rest. Blood examination has shown that secretions are present at the menstrual crisis that are not found at any other time, and it is almost certain that, even in mammals subject to hæmorrhage, the flow is not the only way in which these substances are excreted. The intensity of the menstrual changes varies with latitude and season; the most favourable time for conception in our latitudes is the month of May. This probably corresponds with the general biological quickening-up that all creatures experience at the end of winter, and has been shown to depend to some extent on the lowering of the lecithin content of the blood, which is raised in winter and which counteracts the secretion of the interstitial tissue of the ovaries.

On this view menstruation is the compromise with Nature allowed to females who are not fertilised when they come on heat, and just so far is menstruation a "natural" process. The lives of many women show that the price is no very heavy one, and the psychological factor in dysmenorrhœa may prove, when more is known about it, to play a major part. It is permissible to conjecture that the woman with painful periods is paying not only for her failure to conform to Nature's law that she should conceive every time she menstruates, but also for her lack of adaptation to environment—physical, moral, and mental. The Victorian spinster suffered, not only because she did not have children, but also because she took no exercise and because she failed to make psychological terms with her sex. Modern women are more closely adapted to realities; they are better ventilated, both in body and mind.

## MENTAL DEFICIENCY AND IMPRISONMENT.

FOR the third time in little more than a year public attention has been invited to the fact that the full value of the Mental Deficiency Act is lost, the community is injured, and the prison establishment is unfairly burdened because the Act contains the unfortunate requirement that the condition of mental defect must be shown to have existed from birth or early age. Twelve months ago the Prison Commissioners pointed out this flaw in the working of the Act[1]; some months later the Committee on Sexual Offences recommended an amendment to remedy it[2]; and now the Prison Commissioners in their recently issued report for the year 1924-25[3] have emphasised the same point again. The requisite proof of mental deficiency from birth or early age, they say, frequently cannot be given; if a parent or guardian chooses to make mis-statements on the subject when asked for information, it is difficult to controvert them. Medical officers can bring forward cases of unmistakable mental defect, yet they find it impossible to give a certificate in the absence of the required particulars of the patient's early history. As in the case of insanity, so in the case of mental deficiency, it should be the patient's present condition which should determine the issue of certification. Dr. G. B. Griffiths, the Medical Commissioner, in his contribution to the recent report, explains the significance of the wording of the Act as it now stands. In the past four years 985 mental defectives who had come in conflict with the law have been dealt with under Sections 8 and 9 of the 1913 Act and, instead of being sentenced to imprisonment, have been either certified and removed to institutions while undergoing sentence or else have been sent to a "place of safety" pending the presentation of a petition on their discharge from prison. Thus nearly a thousand persons have been withdrawn from the army of habitual offenders, and the gradual decrease in the numbers of our prison population and the general diminution in crime may be attributed in part to the segregation of these persons in institutions. But clearly there are still many mental defectives whom, because of the flaw in the Act, it is impossible to certify. Prison, says Dr. Griffiths, is no place for them since they are unfit for prison discipline, and a few weeks or months of imprisonment has no curative and possibly no deterrent effect upon them.

The Commissioners' report (as in previous years) makes the further suggestion that the Mental Deficiency Act might, with advantage to society, be extended to provide proper care and control for cases of subnormal mentality and mental instability. The medical officer of Brixton prison points out that cases of mild senile or other dementia are unprovided for; persons of this type commit trifling offences often because they are unable to earn a living. They are not certifiable as insane, yet are no longer able to look after themselves in our complicated social system. The medical officer at Holloway similarly mentions (as last year) the type of debilitated women who have become defective either through senility, alcohol, or their mode of life. They are not at present covered by the Act, yet are unfitted for employment, and on release from prison drift into the workhouse or else return to prison again. Two other interesting points from the medical officers' reports may be mentioned. One is the reference to post-encephalitic delinquents at Brixton, cases resembling congenital defectives in their mental characteristics, apparently hopeless and likely to increase in number unless and until some sure method of curing or protecting against encephalitis lethargica is discovered. The other point is made by the medical officer of Birmingham prison, who boldly says that the whole question of the correct treatment of offenders is a purely psychological matter. No prison punishment, he remarks, can be inflicted without the medical officer's concurrence. "It is but a short and logical step to the position that no sentence of imprisonment should be awarded, or any order of court made, without due attention being paid to the findings of an adequate medical examination." Judicial comments upon this perfectly rational proposition would be entertaining. Mr. Justice Shearman has just been telling a jury in a criminal case that it is not for "Harley-street" to decide questions of insanity. What will he say to the suggestion that "Harley-street" should pass sentence?

## THE COUNTRY DOCTOR IN FRANCE.

IN the *Petit Journal Illustré* (Paris) of March 7th M. Jean Lecoq has written an interesting article entitled Le Médecin de Campagne. After citing Balzac and the good Dr. Benassis, the friend of the poor who was always remembered by them in their morning and evening prayers and who accepted money from the rich only to buy with it medicaments for the poor, the author next quotes Flotow in the old and favourite comic opera, "L'Ombre," where the jolly médecin de campagne always seasons his treatment with a happy couplet, so that as soon as the sound of the neck-bell of his mare is heard, "le malade sourit, et bien souvent guérit," which agrees with the opinion of Molière that "lorsque le médecin fait rire le malade, c'est le meilleur signe du monde." He then cites Humbert de Romans, an authority in his time, and the rules he laid down for his disciples to follow in their medical treatment, but which dealt more with their habits, deportment, table manners, and light conversation. His counsel was that "as you probably won't be able to diagnose the complaint, tell the patient that he has obstruction of the liver, and when he replies 'No, master, it is in the head that I suffer,' reply quickly, 'Ah, that comes from the liver.'" Also, he suggested, "make good use of the word 'obstruction' as they won't know what it means and they shouldn't know." France to-day, says M. Lecoq, contains about 21,000 doctors, a figure which is a little surprising, for it implies considerable scarcity of medical service in some districts. For it must be remembered that the large class of *officiers de santé*, abolished in 1892, is very nearly extinct, something under 500 names only now remaining on the official list In the time of Louis Philippe, that is to say, about 80 years ago, there were less than 8000 doctors and many districts were totally deprived of them At the time of the Franco-German war, in 1870, France had 14,000 doctors, showing a rise in the numbers which had no relation to increase of population. On the eve of the recent war there were 20,000 qualified medical men in France, and complaints of the overcrowding of the profession were heard, but, of course, chiefly in the towns. In Paris to-day there is one doctor for fewer than 900 inhabitants, which is much the proportion that prevails in this country save in particular centres. But certain departments have not enough doctors to deal with disease in modern manner, allowing that conditions of life in the mountainous districts will always be difficult, as they still are difficult with us in Scotland despite special legislation to meet the needs of the Highlands and Islands

[2] THE LANCET, Jan. 2nd, 1926, p. 45.

[3] Cmd. 2597. H.M. Stationery Office. 1s. 3*d*.

' How many doctors," asks M Lecoq, "have vegetated in the Paris suburbs who might have had a larger and happier life in the country if they had not allowed themselves to be caught by the bait of the large town with its often illusory promise of fortune and glory" And he proceeds to point out that conditions of country life are now different, for no longer does the doctor's old nag joggle the life out of him and restrict his range of visits , his little motor-car takes him at his ease for miles and, moreover, the country populations are now more prosperous and can pay better They no longer consult first the bone-setter and the 'old wife' who knew how to set the saints to work and which saints to appeal to for such and such complaints" Cherville, in his book 'Village Studies," depicts the wrath of a peasant who was asked by the doctor three francs for five minutes advice a sum which was as much as he gained the whole day guiding the plough He ought to have had a quarter of an hour at least, he thought, but nowadays says M Lecoq, the peasant understands that time does not enter into the matter like that, and that science has its value and should be paid for In short, with more general well being, more light has entered the rural world, which is so much the better for the country sick and the country doctor M. Lecoq s peroration is: "Thy profession, good doctor, was for centuries hard and profitless but the future will be better than the past. Be like thy predecessors, the curer of the body and the consoler of the spirit, following the resolution expressed by the poet François Fabié, in beautiful lines which thou didst inspire:

*Sauve, le plus que tu pourras,*
De la Faucheuse aux maigres bras
Le paysan qui plante et sème
Jusqu à l'heure où tu t'en iras
Sans regret la trouver toi même.

## THE HUMAN FACTOR IN ACCIDENT CAUSATION

A report has just been issued[1] by the Industrial Fatigue Research Board which may frighten off many readers on account of its statistical appearance, nevertheless, it contains much of great interest Some years ago the Board published an investigation by M. Greenwood and H M. Woods[2] in which an effort was made to measure the influence of the personal factor upon accident causation This investigation was confessedly only a preliminary one The report now issued attacks the problems again making use of new and more extensive data. Over 16,000 minor accidents which occurred in a variety of factories are submitted to careful statistical analysis The writer, Miss E M. Newbold, appears at times to be over-cautious in drawing her deductions Suffice it to say that the conclusions arrived at in every way substantiate those of previous inquiry The average number of accidents is found to be influenced by a comparatively small number of multiple accident people, individuals with an innate tendency to sustain accidents Nevertheless, on the whole the people with most accidents have usually been a shorter time in factory employment. Possibly those predisposed to accidents become naturally eliminated. The chance of an accident occurring appears to differ for each person, even though employed on the same work. A useful table is given from which an answer can quickly be obtained to the question whether the accidents in any department are due mainly to the accident risk associated with the work, or to the presence of a few people who have many accidents, the method of using the table is explained Experience is an important factor, and the level of the accident rate varies inversely with the experience of the workers but even after allowance is made for this, a definite tendency is found for younger workers to have more accidents than older ones. This tendency helps to explain why sudden rises in accident-rates are associated with increased trade, due to the engagement of young as well as green labour A curious fact emerges that the accident-rate and the death rate with respect to age are opposed; whereas the former falls with age, the latter rises The accident death rate rises, due to increased 'tendency to die" among older people, rather than to any increased "tendency to have accidents." The same fact holds true for illness—viz., the average duration of any single case increases with age. Another interesting point is the evidence found that the number of accidents an individual has is positively associated with the number of times he falls sick. So that in the saying what is the matter with the sick is their tendency to be sick," the word sick" *must be held to include a tendency* to accidents Many attendances at factory ambulance rooms are on account of accidents which take place away from the works. Examination of these records brings out the fact that the same people who are *unfortunate* in the factory *seem also to be unfortunate* at home, and that there really are some people in whose hands knives and plates are not safe The importance of the personal factor in accident causation is difficult to exaggerate, since over 80 per cent. of all accidents have no mechanical origin and not more than 5 per cent can be attributed to factors outside human control What holds good for accidents taking place within the factory walls is presumably also true for the occurrences of ordinary life, but these latter do not lend themselves to careful investigation. Moreover, the association between sickness and accidents is significant. How few of us appreciate that when we *sustain some slight injury* we are really not quite fit, and that such incidents as multiple losses of property, such as leaving an umbrella in the train, have the same meaning While congratulating Miss Newbold on the way in which she has overcome the difficulties inevitable to such an intricate investigation, we are glad to learn that the whole subject is being further investigated, particularly to ascertain how far a tendency to sustain minor accidents may be taken as a criterion to succumb to major accidents

## MEDICAL AND DENTAL REGISTERS.

We have just received copies of the Medical and Dental Registers for 1926 and of the Medical and Dental Students Register for the corresponding period. The total number of persons registered under the Medical Acts from the beginning of registration in 1858 up to Jan. 1st 1926, is 98,308, and 52 531 are said to remain on the Register as made up on the last day of 1925 These are 2073 more than in the 1925 Register, distributed over the three sections into which the Register is still divided, although some of this increase may be illusory, for an error seems to have crept into the number in the Foreign List as given in Table D, where the total of 232 is 121 in excess of the 111 names given in the 1925 table, although only 8 names have been added by registration. These two figures have, it seems, inadvertently been added together, and the number should therefore, in accordance with our calculations, be reduced by 111. The same oversight seems to have affected a figure of 3243 given in the same table for the Colonial List. From a study of Table E we deduce the total number of registered persons as 50,035 on Jan. 1st, 1925, and 51,737 on Jan. 1st, 1926, an increase of 1702 names. The excess of numbers in any year over the previous is, of course, due to a balance between the number added by registration and the number removed. The numbers added by registration are given in Table E as 1246 for England, 736 for Scotland, 406 for Ireland, 173 for Colonial, and 8 for Foreign, while, of the 947 names removed, 794 were removed on evidence of death, 1 on ceasing to practise, 146 under Section XIV., and 6 under Sections XXVIII.–IX. of the Medical Act. We learn that 1602 copies of this Medical Register have been printed, 872 of which have been earmarked for medical practitioners registered in 1925, of which it is curious to note the expectation that 472 will be claimed by Scottish practitioners. The number of copies available for sale is 400, an edition which is likely to melt away under the demand due to the present interest in the General Medical Council and its doings. The only substantial addition to the contents of the book is a reprint of the Medical Act, 1925 (Irish Free State), passed on Feb. 21st, 1925, to continue in force for one year only from that date. The Register contains, as everyone knows, the full text of all the Medical Acts from the first Act of 1858, the names of members of the Council, and copies of the warning notices issued to registered persons whether medical men or dentists. We cannot help regretting that the admirable memorandum written by the Registrar of the Council on the constitution, functions, and procedure of the Council has not been included in the volume. The Dentists Register contains 14,199 names, of which 14,111 are United Kingdom dentists, and of these 5841 possess licences or degrees in dentistry. There is an increase of 381 names on the 1925 Register; during the year 1925, 546 names were removed, 115 on evidence of death and 425 under Section 7 of the Dentists Act, 1921; and 400 names were restored, mostly under the same section. This Register contains no important additions in the text, apart from the revised list, and enclosed with it as usual is the list of bodies corporate carrying on the business of dentistry and the names of the directors of these bodies. The lists of medical and dental students registered during the year 1925 contain the names of 1070 medical students and 191 dental students, being respectively 27 more and 9 less than the corresponding figures last year. All these three volumes are published for the General Medical Council or the Dental Board by Constable and Co., Ltd., the prices being respectively 21*s.*, 12*s.*, and 7*s.* 6*d.*

DONATIONS AND BEQUESTS.—Among other bequests the late Mr. Warley Pickering, of Hutton Hall, Guisborough, Yorks, left £1500 to the North Riding Infirmary, Middlesbrough, and £1500 to the North Ormesby Hospital, Middlesbrough.—Mr. William Alfred Sammes, Windsor, who left £23,888, after various bequests amounting to £2000, left the residue of his property between St. Andrew's Hospital, Clewer, St. John's Home, Clewer, and King Edward VII. Hospital, Windsor.—Miss Laura Lushington, of Reading, Berks, left £100 to the Samaritan Fund of Guy's Hospital. —Mrs. Elizabeth Crawford-Hayes, Clarges-street, Mayfair, W., widow of Dr. Thomas Crawford-Hayes, left the residue of her property to King's College Hospital, London, for Crawford-Hayes beds. The amount available for this purpose will be about £19,000.—Miss Amelia Broadbent, of Buxton, left £2000 in trust for her cousins for life, and then £1000 to the Manchester Royal Infirmary and £500 each to St. Mary's Hospital, Manchester, and Ancoats Hospital and Dispensary.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXV.—ACUTE EMPYEMA IN CHILDREN.

SUCCESS in the handling of a child's empyema depends in no small measure upon early diagnosis. Speedy detection of the pus and prompt application of requisite treatment minimise the risk to life and promote the early and complete re-expansion of the lung, which is essential to the obliteration of the cavity and the final cure of the disease. Fatalities, unhealed sinuses, and chest deformities—"chronic empyemata"—are the penalties more often of casual clinical observation than of ineffectual treatment. Before deciding upon what treatment is applicable to any individual case, it is necessary to appreciate the type and virulence of the abscess and its precise significance in the general clinical picture. In every empyema evacuation of the pus from the pleural cavity is urgently called for, but the way in which this is done may make all the difference between success and failure; one routine treatment for all cases—e.g., opening the chest and inserting a drainage-tube—while it may cure many, will certainly prove unavailing in some. When the exploring needle has confirmed the presence of pus, the following points must be carefully considered before deciding upon the wisest method of evacuation: (1) The age of the child. (2) The size and situation of the empyema. (3) The general condition of the patient, especially as to whether we are dealing with an empyema which is: (*a*) *synpneumonic* (Cameron and Osman [1])—i.e., coexisting with an active pneumonia; (*b*) *metastatic* —i.e., a local manifestation of, or metastasis from, some distant focus, the child being gravely ill from the generalised infection; (*c*) *metapneumonic.*

The primary object is to save the child's life and in many cases—notably in infants and in the synpneumonic and metastatic types—immediate thoracotomy is attended with grave risk. Fortunately, in these cases the exudate is often conveniently thin and aspiration mechanically simple.

For evacuating an empyema the following methods are available: (1) Aspiration: (*a*) intermittent; (*b*) continuous. (2) Thoracotomy—with or without resection of rib and followed by: (*a*) closure of the opening; (*b*) with drainage either "closed" or "open." (3) A combination of (1) and (2).

### *Intermittent Aspiration.*

Potain's apparatus is commonly employed. The needle or trocar of the aspirator is introduced along the tract of the original exploring needle. The chest wall should be locally infiltrated with ½ per cent. novocaine, or, better still, the child anæsthetised with $N_2O$ and oxygen. The pleural cavity is emptied as completely as possible, the needle withdrawn, and the puncture sealed. The aspiration is repeated as necessary. This simple procedure may suffice where the chest contents are merely turbid serum, but where the empyema is frankly purulent it is very unlikely that all the pus and debris will be really evacuated from the cavity even by repeated aspirations of this type; and though the case may recover, it is almost certain that some deficiency of expansion and chest deformity will remain. Nevertheless, it may be of life-saving value as an adjunct to treatment in certain cases. In very large empyemata —where there is considerable cardiac displacement and the child's respiration is seriously embarrassed— it is always wise to aspirate by this method a quantity of the pus 12 to 24 hours before proceeding to thoracotomy. The operative risk in such cases is thereby sensibly diminished. In bilateral empyemata, in the synpneumonic or metastatic type of case, where an immediate thoracotomy is dangerous, timely aspiration may tide over the acute phase, a successful operation being performed later

---

[1] THE LANCET, 1923, i. 1097.

### *Continuous Aspiration.*

In this procedure the aim is to evacuate the empyema gradually by continuous suction drainage, and to keep the cavity empty until the lung has fully expanded and the discharge has ceased The method advocated by F. J Poynton and F N Reynolds is:

The child is anæsthetised. A nick is made in the skin and a special trocar and cannula (size 10 English catheter gauge) is introduced into the empyema cavity The cannula is fitted with lateral flanges bearing slits for tape, as in the case of a tracheotomy tube This enables the instrument to be tied comfortably to the chest wall. If necessary this fixation can be reinforced by strips of strapping. The trocar is withdrawn, and rubber tubing stretched upon an introducing rod is passed through the tube of the cannula into the chest. The tubing should project just beyond the cannula and must be of such a bore (No. 0 rubber catheter) that when the introducer is withdrawn it expands to fit the cannula in a perfectly airtight manner Any misfitting of these two tubes will defeat the subsequent procedure. The rubber tubing is now connected up with a suction pump and receiving bottle. The continuous 'water drip' suprapubic pump, designed 20 years ago by E White, pharmaceutist of St. Thomas's Hospital (Allen and Hanburys) answers admirably The contents of the empyema are slowly evacuated into the receiving bottle. The apparatus requires supervision and occasional adjustment to prevent kinking or blocking by flakes of lymph, but works efficiently in suitable cases.

This method has a wider scope than the intermittent form of aspiration, in that it may be used alone throughout in some cases, and has been shown to really drain the empyema thoroughly. It has the great advantage of requiring only a very simple operative procedure and of obviating the necessity of after dressings. The comfort of these children whose empyemata are undergoing gradual transference to a bottle by their bedside is remarkable. The disadvantages are mainly technical. The requisite supervision of the apparatus has been mentioned Where the pus is thick and fibrinous masses are present the aspiration will be unsatisfactory and should not be attempted except to tide over a crisis in bad cases. But the main difficulty comes in deciding when the drainage may be discontinued In successful cases in seven to ten days the discharge becomes serous, the expansion of the chest and the air entry into the lung approximate to normal, and the tube may be withdrawn, and a dry dressing applied to the puncture In other cases the indications are less clear and withdrawal of the tube may be followed by a disappointing re-collection. In practice the method is valuable when a major operation is undesirable, as in infants under 2 years

### *Thoracotomy*

The majority of empyemata in childhood, at any rate after the first two years of life, are of the metapneumonic type—i e., they are residual abscesses remaining as the unfortunate legacy of a quiescent pneumonia. The pus is thick; fibrinous clots have separated out and enmeshed leucocytes and organisms in great numbers, and then settled to rest at the base of the cavity and on the surface of the visceral and parietal pleura, which is greatly thickened and "felted" in consequence. Possibly adhesions have formed and loculi of pus have become shut off from the general abscess cavity. The only satisfactory treatment is to open the cavity freely and evacuate and cleanse it completely A preliminary aspiration, 12 hours or so before operation, is advisable where the empyema is of large size, with cardiac displacement and respiratory embarrassment, or where the child's condition appears at all desperate.

The steps in the operation of thoracotomy are

*Anæsthetic.*—Warm ether and oxygen is the wisest anæsthetic for these cases. In the absence of active pneumonia there is no risk provided the ether vapour is warmed

*Position.*—The child is turned on its face and then tilted so as to bring the affected side uppermost; this position is stabilised by flexing the leg of the same side and placing a suitable pillow or sandbag along the front of the chest.

*Operation.*—The site usually chosen for opening the chest is the posterior axillary line about the level of the eighth or ninth rib The exploring needle will usually have withdrawn the pus at about this point. In cases where an apical or interlobar empyema has to be negotiated, the chosen site must be varied accordingly In such cases it is always wise to explore with a needle and syringe first, and then to follow the needle track carefully in making the incision

A segment of rib of sufficient length to permit easy exploration and toilet of the empyema cavity should always be resected. A simple intercostal incision should only be made where the conditions preclude a more thorough operation The skin and muscles overlying the selected rib being fixed with the left hand, an incision of about 3 inches is made straight down to the rib Bleeding vessels are ligatured and the skin closed off The rib is then isolated by stripping the periosteum all round the bone, and the required length of bone is resected The intercostal vessels and nerve are stripped away with the periosteum and are not likely to be injured The parietal pleura is now incised and the opening gradually enlarged with sinus forceps. The pus should be let out slowly and sucking in of air should be prevented as far as possible by keeping the opening covered by gauze packs. Coughing and laboured respiration, common at this stage, render such protection additionally necessary The liquid pus having been evacuated the operator proceeds to remove all fibrinous masses and to cleanse the pleural cavity Any adhesions are gently broken down with the finger and any shut-off loculi of pus opened up Long curved dressing forceps carrying suitable lengths of gauze serve admirably to clean the fibrinous deposits from the walls of the cavity. Usually, as the visceral pleura is cleared, the lung expands towards the chest wall, and when this occurs the outlook is good. The drainage-tube inserted should be large (18–20) and should only just enter the pleural cavity If possible the parietal pleura should be carefully sutured around it Finally, the muscles of the chest wall are brought together by one or two catgut stitches and the skin edges closed around the tube by interrupted stitches of silkworm gut Closure of the wound without drainage is not to be recommended; it usually fails.

### *Post-operative Treatment.*

The further disposition of the drainage-tube has to be decided on. We may cut the tube short, put a safety pin through it and put on the dressing—the "open" method Frequent change of dressings are required which are trying to the child. Exposure of the open tube leads to coughing, discomfort, and sucking in of air, a device to avoid this (suggested by W H. C Romanis) is to clamp the tube with a small pair of artery forceps. At each dressing these are released The accumulated pus is allowed to run out and the clamp reapplied and incorporated in the dressing Perhaps the best method of all is to leave the tube long and to lead it away below the surface of some antiseptic fluid in a sterile basin beneath the patient's bed. A syphon action is started, which will keep the discharge constantly flowing into the basin. This, which we may term the "closed" method, adds greatly to the child's comfort Dressings must be carried out with the most rigid precautions as to surgical cleanliness Secondary infection, so easily introduced, yet working its havoc so stealthily, is seldom blamed for a disappointing end-result, but is often responsible therefor Tube drainage should be discontinued as soon as possible, indication for discontinuance being a thin, serous, and scanty discharge with normal temperature and good air entry.

Every effort must be made to promote the early expansion of the lung. Within three days of the operation the child should take deep breaths while the sound lung is compressed with the hand. Later the sound side of the chest may be strapped. Once the tube is out the child should be encouraged to lie on the good side and deep breathing exercises should be continued. Woulfe's bottles charged with attractively coloured fluids are usually employed with the object of encouraging expansion.

These cases should be nursed in the open air if possible Convalescence should be completed by a stay in the country or at the sea, and graduated physical exercises maintained to complete the restoration of respiratory function. The standard of final cure should be a full degree of chest expansion as compared with the sound side and no thoracic or spinal deformity

## ACTIVE IMMUNISATION AGAINST DIPHTHERIA.

### THE PRESENT POSITION.

BY R. A. O'BRIEN, C.B.E., M.D. MELB.

*(From the Wellcome Physiological Research Laboratories, Beckenham, Kent.)*

FOR the modern history of active immunisation in man we need not go further back than to Theobald Smith's suggestion (1909) that mixtures of toxin and antitoxin should be used for the immunisation of human beings. The first attempt to immunise considerable numbers of human beings was made by von Behring who examined various combinations of diphtheria bacilli, toxin, and antitoxin; the method settled down (1913) into the one that has been in general use until recently in Austria and Germany. Broadly speaking, this consisted in the use of an under-neutralised mixture of toxin and antitoxin—i.e., one in which there is slightly more toxin present than can be neutralised by the quantity of antitoxin. The mixture is therefore toxic to animals.

### *v. Behring's Mixtures.*

With regard to von Behring's mixtures, Dr. van Boeckel (1924) in his report to the League of Nations writes:—

> "We do not know the exact composition of von Behring's T.A. mixtures. The fact that they are administered intradermally is not calculated to simplify the technique, which is rendered still more complicated by the fact that the proper sensitising dose has to be discovered before the vaccinating dose can be administered."

This method seemed to be rather difficult to carry out in practice and is falling into disuse in its original home where American mixtures and practice have recently begun to attract attention.

A new and brilliant chapter was opened by Park and co-workers in New York in 1913. They first used a mixture of toxin and antitoxin containing in 1 c.cm. 3 L+ doses of toxin, under-neutralised to such an extent that doses of from 1 c.cm. to 5 c.cm. produced paralysis or death in guinea-pigs. Within the past few years, Park has replaced his original mixture by a second toxin antitoxin containing in 1 c.cm. only 0·1 L+ dose of toxin, though in each cubic centimetre of this mixture the same amount of toxin is left unneutralised as in the original 3 L+ mixture. This second mixture was tested on man in parallel with the original one and gave fewer local reactions, whereas its immunising power was probably better. It is now in routine use in New York and most of the United States of America.

The two American accidents in active immunisation occurred apparently with preparations similar to Park's original mixture. It is now possible to make some statement about the first of these accidents, that at Dallas, the cause of which is clearly understood. A certain volume of toxin added to a certain volume of antitoxin may give a neutral mixture—i.e., one that is harmless to guinea-pigs when injected. But if the toxin be divided into two portions, the first of which is added and thoroughly mixed with the antitoxin, while the second portion is added subsequently, a toxic mixture may result. This is the well-known Danysz phenomenon. The original tests of the mixture used at Dallas had been carried out thoroughly and were apparently completely satisfactory. Owing to an unfortunate mistake the applicability of the Danysz phenomenon to the mixture in question, when, after the first tests the proportions of toxin and antitoxin had to be adjusted, was overlooked, and a toxic mixture resulted. The second of these accidents (Concord, 1924) was caused by the accidental exposure of a mixture to intense cold for several days, when sufficient toxin was released to cause severe reactions in several dozen children. There were, fortunately, no deaths. The explanation of this phenomenon has been given by Glenny and co-workers (1925) in this country. Now that this risk is recognised it is very unlikely that this same mishap will again occur. A very large number—probably several hundred thousand—injections of these American mixtures have been given with complete safety except in the two well-understood instances mentioned, and with excellent immunising efficiency.

With regard to the Vienna (Baden) accident (THE LANCET, Oct. 3rd, 1925, p. 713), it has apparently been impossible to obtain for examination in England a specimen of the mixtures used, so that no close comparison of the Vienna lethal preparation with the American or English mixtures has been possible. It is not easy to deduce from the published account by Helmreich (1925) exactly how the mixture was constituted, although it is clearly stated that it was made of toxin and antitoxin. Presumably the aim was to produce a mixture similar to those used by Park. If, as is suggested, a non-toxic mixture of toxin and antitoxin dissociated under ordinary conditions of storage and became toxic, this phenomenon has not been met with in the very extensive experience of American and English workers.

### *Detoxicated Toxin.*

The next development in the history of immunisation was the use (without antitoxin) of toxin which had been so treated as to deprive it of most or all of its original toxicity while leaving its immunising power still high. In this "toxoid" class come the aged toxin, &c., used by Park (1923), the formalinised "toxoid" made by Glenny and Hopkins (1923), and used by O'Brien and co-workers in England, and the formalinised "toxoid" or "anatoxin" used by Ramon and colleagues (1924) in Paris.

Theoretically, preparations of this toxoid class should be preferable to Park's first or second mixtures, for they can be made completely atoxic to the guinea-pig and they are free from the additional complication of having antitoxic serum present. These toxoids are being tried cautiously in the three countries mentioned; it is possible that they will eventually entirely replace the other prophylactic preparations, but it is too early yet to predict this with any certainty. The immunising power of toxoid is high, but it is apparently rather liable to cause reactions when injected. The concentrated toxoid preparations of Watson and Glenny (1924) may be added to this class; though they produce a high immunity in animals and are atoxic, they have not yet been used in human practice to any large extent.

Another class of prophylactic is represented by the toxoid antitoxin mixtures made and used widely in England. Glenny and co-workers (1924) discovered that if one makes a toxin non-toxic by treatment with formalin—a preparation which has high immunising power—and adds a certain volume of antitoxin to the toxoid, the immunising power of the toxoid is not materially reduced. A typical mixture of the kind would contain in 1 c.cm. about 0·1 c.cm. of "toxoid" made by formalinising toxin with an original minimum lethal dose of between 0·002 c.cm. to 0·001 c.cm. until the lethal dose was reduced to about one-hundredth of its former value or, better, to the stage where 5 c.cm. produced no symptoms in guinea-pigs. In addition to the toxoid, the mixture contains a quantity of antitoxin varying from 25 to 50 per cent. of the amount corresponding to the original neutralising value of the toxin. The mixture which gives the best immunity index is the one chosen for use. This combination is non-toxic to guinea-pigs but gives excellent immunising results in these animals and is apparently a "safe" mixture. Many thousands of doses have been given during the past two years. Even four or five years ago, when the first toxin antitoxin mixtures of the American type were used in England, the standard of toxicity adopted was below that permitted by the official Washington regulations. These latter allow the use of mixtures of which 1 c.cm. will produce paralysis in all the animals injected and death in a small number.

It was found by the aid of the Glenny-Allen (1923) "immunity index" that it was possible to prepare toxin antitoxin mixtures of such low toxicity that 1 c.cm. did not produce paralysis or death, while a dose of 5 c.cm. would cause paralysis or death in either none or at most a small percentage of the guinea-pigs injected, and yet would rapidly produce immunity. Most of the published work in England was apparently done either with mixtures of this type or of the toxoid antitoxin type previously mentioned. These latter preparations appear to have a double margin of safety. They contain toxoid mixed with a quantity of antitoxin and thereafter diluted ten times. The toxoid is itself almost or completely devoid of toxicity. This change from toxin to toxoid is apparently an irreversible one, for in all the intense study of this field by various workers during the past few years there has arisen no evidence suggesting that toxoid in this condition can revert to toxin. Even if this very unlikely change took place and some of the toxoid were reconverted to toxin, the mixture contains sufficient antitoxin to neutralise a large amount of toxin.

### *Lines of Future Progress.*

With regard to possible progress in the future, the main effort is being directed along three lines. The first is to provide active immunisation for children of pre-school age who are likely to be exposed to diphtheria. Most of the work hitherto has been carried out with children aged 6 and upwards, but a great deal of diphtheria occurs in younger children. The second is to increase the immunising efficiency of the prophylactic so that one could obtain the same efficiency of immunisation with two injections or even one, which one now obtains with three. Along these lines progress must be slow. It is easy to make immunising mixtures of very high efficiency in the laboratory. Thus Glenny and co-workers have described a preparation which will make animals negative to the Schick test in 12 days, but the transfer of such work to human practice must be slow, for the greatest caution is necessary. The other effort is to shorten the number of tests and injections by combining them. Park is directing effort to a mixture which when injected will indicate the response to the Schick test and at the same time will act as an immunising agent.

In England there are at present (1926) being tried mixtures which will, when injected intracutaneously into animals, produce a Schick test reaction, and at the same time supply an efficient immunising stimulus. One can thus, when each immunising intradermic injection is given, get an indication of the condition of the patient and know exactly when to cease the injections.

MANCHESTER HOSPITALS.—The deficit on the St. Mary's Hospital, which treated 17,201 patients last year, amounted to £1123. To make room for extra beds at the Whitworth-street West Hospital a house in Victoria Park will be made into a nurses' home, and the number of beds at the High-street Hospital is also to be increased.—The Manchester and Salford Hospital for Skin Diseases treated 12,230 out-patients and 102 in-patients. The ordinary income was £9227 and the expenditure £9150. A new wing with a department for artificial sunlight, accommodation for nurses, and seven more beds was begun in September. The cost will be £11,500, of which £11,225 has been received. Local authorities have extended travelling facilities to allow patients to take advantage of the hospital's treatment.

## NORTHUMBRIAN SURGERY.

INTERNATIONAL congresses have done much to standardise the teaching and practice of scientific surgery throughout the civilised world; it is these meetings with the subsequent reports of their proceedings which have brought it about that there is hardly a hospital in any country in which—for example—the antiseptic treatment of wounds, the procedure for the radical cure of hernia, and the technique for the production of anæsthesia are not substantially the same even while varying in detail. But the injuries to which the people of an area are subject differ, and so accordingly do the diseases with which surgery has to deal, and the views and the ingenuity shown by the local surgeons maintain a certain local flavour, sufficient to render a visit to any one surgical school stimulating and useful to members of another. The Royal Victoria Infirmary at Newcastle or the Hospital—it goes locally by either name—serves an area with over a million inhabitants, of whom a large proportion are engaged directly or indirectly in shipbuilding or coal-mining. Open-handed to a degree when times are good, the working population of what may be termed for convenience *Northumbria*, now contributes far the larger proportion of the cost of maintaining their beautiful hospital and have acquired with good reason a ruling voice in its discipline and organisation. This fact carries with it an interesting consequence, for local patriotism appears to forbid the miner to elect any but his geographical kith and kin to the service of the hospital, and, as a result, the teaching staff in surgery, as well as the demonstrators and assistants in clinical surgery, hold, with slight exception, surgical degrees of the University of Durham and have been born and brought up in its neighbourhood. Mr. Rutherford Morison, Emeritus professor, was born at Hutton Henry, Co. Durham; Prof. Brunton Angus is a native of Newcastle; and the lecturer on surgery, Mr. G. Grey Turner, was brought up in the neighbouring town of North Shields. And these Northumbrians have had to deal with, and are dealing with, conditions which give a particular direction to their science and their practice. This is not to say that they are insular or parochial, for as is well known they make a point of visiting other centres, but they develop their particular work in directions that are locally indicated.

The shortage of beds, serious elsewhere in the country, is especially severe in Newcastle, and as a consequence it is the practice of the infirmary to give priority to the more acute and urgent surgical cases, cancer cases, and industrial injuries, where alleviation or cure means restoring the wage-earner. Straitened finance has so far hindered the incorporation of the beds in the adjoining pensions hospital, although, should nothing intervene to alter plans, this splendid additional accommodation will be available in two years and will supplement the present beds by another thousand. While among the patients for whom space is always found are those who present operable tumours, fractures naturally play a large part in the hospital experience, for injuries in mines and shipbuilding are frequently severe, so it is of real interest to note that the practice of the infirmary in regard to compound fractures has assumed a routine character slightly different from that in force elsewhere. The wound is excised as soon as possible, washed with 1 in 20 carbolic, dried with methylated spirit, and rubbed with Rutherford Morison's bipp, which is also applied to the ends of the bone before doing what is necessary in the way of fixation. For simple fractures it is not unusual to lash round the bone with No. 3 chromicised catgut, and experience is in favour of the introduction of an intramedullary peg of beef bone. Some of the surgeons prefer to use the bismuth paste made with 1 in 20 carbolic rather than paraffin, which is less easy to apply evenly to all parts of the surface. Derangements of the knee-joint are also common in a community whose male youth when not at their strenuous work are largely addicted to football, while the miner is obliged to work in peculiar positions often far away from the possibility of help. Thus a radical method of dealing with a torn internal cartilage has been found necessary at Newcastle. It is Mr. Turner's usual practice to make a transverse incision on the inner side of the knee. Through this the cartilage is cut from its anterior and lateral attachments; it is then dislocated forwards and cut through as far back as possible. Only a small portion then remains, and this slips back between the condyles, where its presence is harmless. Men are refused work in the mines for recurrent synovitis, but not after a successful radical operation has been performed—a most practical testimonial to the method which has been evolved. Abdominal emergencies play a large part in the miner's life, and here the pressure on the infirmary has grown steadily in recent days, beds tending to become filled on account of earlier diagnosis by local practitioners—indeed, Mr. Turner has frankly admitted sending away cases diagnosed outside the hospital as appendicitis, which cases had returned later with full-blown symptoms. Exposure and changes of temperature result in the prevalence, not alone among the working class, of fibrositis in various forms, and Prof. Angus has given a particularly interesting demonstration of Dupuytren's contraction for which he had performed Tagliacotian grafting with results still remaining good after three to five years.

The practitioners of the district are welcomed to the teaching of the infirmary, their readiness to overfill the institution, however embarrassing, being counted to them for righteousness. Teaching in clinical surgery has developed largely but independently on lines comparable to those of Theodor Kocher at Berne. In the intervals of operating Mr. Turner, for example, passes in review the various aspects of the case in hand by using a hanging ground-glass screen in the ante-room of the theatre on which are projected pictures from a lantern in the corridor outside. A recent clinical lecture on the treatment of a deranged knee-joint, which lasted four minutes, began with portraits of Lister and William Hey, with a picture of the latter's saw; then followed a remark or two on asepsis as applied to the knee-joint; the anatomy of the cartilages was reproduced from Gray's text-book, and diagrams were given of the common types of tear in the cartilage. A diagram showed the incisions and the position of the internal lateral ligament and now the interrupted sutures in the capsule allowed of seepage of fluid and avoidance of pain; a schedule of the after-history of a series of 24 cases operated upon 9 to 13 years previously brought the lecture to a conclusion, with a portrait of Sir Robert Jones as a pioneer in this branch of practice. At a recent demonstration to visiting surgeons other subjects of interest brought forward included a series of cases of cleft palate which had been operated upon at various ages and which illustrated the facility with which the normal speech is acquired in direct proportion to the early restoration of the soft palate; several cases of transplantation of ureters into the sigmoid colon for various irremediable conditions of the bladder in which rectal continence of fluid was gradually acquired; and a case of complete facial paralysis with suture of the spinal accessory nerve into the facial nerve four years after its occlusion. Eleven years after the operation the facial muscles were mobile with little associated movement, and the condition was still improving. Mr. Turner believes strongly in making an abdominal incision over the site of the lesion to be dealt with, rather than in using the median or paramedian incision commonly used by other surgeons. Several cases were shown to illustrate this, none of the patients having any sign of post-operative ventral hernia.

# RECENT CANCER INVESTIGATION:
## STATISTICAL AND CLINICAL.

THE last few weeks have seen the publication of a number of important reports dealing with cancer statistics. Of these, the two volumes published by an International Committee appointed by the Health Organisation of the League of Nations,[1] are most important, both from their authorship and the interest and magnitude of the problem treated. The problem was presented by the mortality statistics of England and Wales, Holland and Italy. These three countries were selected for two reasons by an authoritative committee, under the chairmanship of Sir George Buchanan, appointed by the Health Organisation. Their official mortality statistics are held to reach an equal standard of accuracy, but reveal a considerable difference in the mortality of cancer of the breast and uterus. This is very much higher in England and Wales than either in Holland or Italy. A detailed inquiry seemed, therefore, likely to yield information on some of the factors which determine the incidence of cancer in these organs. The problem is complicated by the fact that the total mortality for women from cancer of all organs is not the same in these three countries. It is lower in Italy than in Holland or England and Wales. In England, Wales, and Holland the total mortality is nearly the same. This means, of course, that the lower incidence of cancer of the breast and uterus in Holland is compensated for by a higher incidence in other organs, and this compensating increase falls mainly on the digestive tract. Cancer of the digestive tract is much more frequent in Dutch women than in English women. Italian women do not suffer from this compensating increase in cancer of the digestive tract. They have, however, a higher incidence of cancer of the uterus than Dutch women, but this does not apply to England and Wales, where cancer of the uterus is more frequent than in Italy. The statistical inquiry into these problems has been entrusted to a subcommittee of statisticians composed of Dr. Major Greenwood and Dr. Janet Lane-Claypon (London), Prof. Deelman (Groningen), Prof. Methorst (The Hague), Prof. Niceforo (Naples), and Dr. Tomaneck and Prof. Pittard (Geneva). The composition of the subcommittee is in itself a guarantee of the soundness of the work done which is presented in the two volumes in an exceptionally clear and succinct manner.

### *Mortality from Cancer of the Breast and Uterus.*

The first volume is the report of the subcommittee of statisticians. The second volume contains a number of reports by Sir George Buchanan, Dr. A. Lutrario, Dr. N. M. J. Jitta, and Prof. M. T. Deelman on the results of clinical inquiries into the differences of the mortality from breast cancer in the three countries. The report of Sir George Buchanan is based on the investigations of Dr. Janet Lane-Claypon which have been published in a separate report issued by the Ministry of Health.[2] Dr. Lane-Claypon has collected by means of a questionnaire detailed material concerning the life-history of 508 cases of cancer of the breast and of 509 control cases who did not suffer from cancer. The inquiry has been placed, therefore, on a very wide basis. It is probably the most extensive statistical investigation on cancer which has as yet been undertaken, and both as regards the organisation and the care and labour involved in carrying it out reflects the greatest credit on those responsible for it. The material presented is very great and does not lend itself to brief summary.

Clinically it has long been known that cancer of the breast is less frequent in women who have nursed their children than in those who have not done so. This clinical experience is confirmed by this report. It holds good for all the three countries. But the report does not corroborate another clinical dictum concerning cancer of the uterus. Clinicians have held that childbearing predisposes to cancer of the cervix. The statisticians, however, conclude from their material that "the higher incidence of cancer of the uterus upon married women is a consequence of the immediate effects of a single parturition" by which is meant presumably the first childbirth, and that women who have borne many children are less, rather than more, liable to cancer of the uterus in comparison with married women who have borne few children. The statistical data do not allow of a distinction being made between cancer of the cervix and cancer of the body of the uterus. Although this is pointed out in the report as a possible objection, the statistical differences are too definite to be invalidated by it.

---

[1] League of Nations Health Organisation, Subcommittee on Cancer. Vol. I.: Report on the Demographic Investigations in Certain Selected Countries. Vol. II.: Report on the Results of Certain Clinical Inquiries relating to Differences of Cancer Mortality in Certain Selected Countries.

[2] A Further Report on Cancer of the Breast, with special reference to its Associated Antecedent Condition. 1926. London: H.M. Stationery Office. 3s. 6d.

Since, then, the incidence of cancer of the breast and uterus is to a certain degree affected by the physiological functions of these organs, it was to be expected that one or more of the various factors connected with the reproductive life of women might account for the great difference in the incidence of cancer of these organs in the three different countries. But this expectation was not fulfilled by the statistical inquiry. None of the numerous factors, including surgical treatment, which were made the subject of investigation, was found to be responsible for the difference in the incidence of cancer of the breast in the three countries. In place of a solution, cancer, with characteristic elusiveness, presents the following paradox. One statistical finding is that women who nurse their children are less liable to cancer of the breast. Another is that the percentage of women who do not nurse their children is higher in Holland than in England. One would expect, therefore, to find a higher incidence of cancer of the breast among Dutch women than among English women. But, as already stated, the reverse is the case.

Another statistical puzzle is provided by the Italian data on cancer of the uterus. Though cancer of the breast is less frequent in Italy than in either Holland or England, Italian women are more liable to cancer of the uterus than Dutch women, but less liable than English women.

### *Local Predisposing Conditions.*

Though the inquiry has not solved the problem which it set out to investigate, it would be a mistake to write down this great effort as a failure. To have established that those factors which are particularly concerned with the functional activity of the breast and uterus, and which are known to affect the liability of these organs to cancer, do not account for the great national differences in the incidence of cancer of those organs is in itself a positive achievement. Its great value lies in the definite elimination of these factors, so that we must now look elsewhere.

Dr. Lane-Claypon's report deals very fully with the local conditions which predispose to cancer of the mamma. Acute suppurative mastitis was found not to be a contributory cause to the later appearance of cancer of the breast, but evidence of a previous injury, chronic non-suppurative mastitis, and hyperplasia occurred more frequently in the history of the cancer series than in the control series. In a detailed discussion on the importance of hyperplastic changes in the breast as antecedents of cancer, Dr. Lane-Claypon accepts the teaching of Sir Lenthal Cheatle, who has recently published further observations confirming his previous work in a very instructive paper.[3] By a study of sections of the whole mamma he has been able to show that the various hyperplastic changes which he has observed in the human breast and which, as he holds, find their termination in cancer are identical in time and sequence with the changes which can be induced experimentally in the skin of mice by tarring and which are known to end in cancer. The numerous excellent figures which accompany the paper lend strong support to his arguments.

### *Cancer in New Zealand.*

Another report,[4] which is geographically circumscribed, derives its chief interest from this very limitation. New Zealand offers certain exceptional features for the statistical study of cancer. It is a self-contained country which has advanced during the past 50 years from a community of pioneers to a community enjoying all the advantages of civilisation without its disadvantages. We mean that the people are prosperous, possess all facilities of education and communication, and have an efficient and up-to-date medical service, while the excessive urbanisation which characterises the civilisation of Western Europe is absent. The people are of Anglo-Saxon descent without much admixture by immigration, so that by a comparison with the incidence of cancer in this country it is possible to test whether the difference in the climatic and social conditions has affected the incidence of cancer. The report shows that the incidence of cancer in New Zealand is exactly the same as in this country.

During the last 50 years there has been a very rapid increase in the recorded death-rate from cancer in New Zealand. The increase is mainly an apparent one, as Mr. Butcher points out in an admirable summary at the end of the report, due to the greater efficiency of the medical service, which in New Zealand, as in all civilised countries, is gradually bringing, by better diagnosis and registration, the recorded death-rate from cancer more and more up to the level of the unknown actual death-rate from cancer. We find accordingly the most rapid increase during the earlier years 1875 to 1900, while during the last 15 years the death-rate has remained nearly on the same level. The increase affects men more than women, because in men the organs chiefly liable to cancer are less accessible than in women, so that they escape diagnosis more easily.

Perhaps the most interesting data of this report are those referring to cancer among the Maoris. The presence of a native population living under the same conditons as Europeans, subject to the same system of registration as regards birth and death, and having the same opportunities for medical treatment, offers exceptional facilities for the study of the vexed problem of the incidence of cancer in native races. The statistics submitted give for Maoris a crude death-rate of only 2·60 per annum per 100,000 living as against a corresponding rate of 8·80 for the rest of the population. Mr. Butcher believes that, for various reasons, the rate for the Maoris is probably understated, but "there is sufficient evidence on which to conclude that cancer is much rarer among the Maoris than among Europeans." If this difference should be confirmed by a careful and detailed investigation into the incidence of cancer among the Maoris, it would afford clear proof of the existence of racial differences in the susceptibility to cancer. There is here a unique opportunity to gain important information on this aspect of the cancer problem.

HOSPITAL BEDS FROM TINFOIL.—The Committee of the Tinfoil Fund of the Ancient Order of Druids reports that last year £1228 was realised by the sale of "silver paper," making a total of £6610 since the fund was started in 1912. It is intended to endow three hospital beds this year, in addition to making small money grants to ten hospitals.

WALTHAMSTOW HOSPITAL.—The Lord Mayor of London, Sir William Pryke, on March 11th laid the foundation-stone of the Thomas Worton Ward and the Leyton and Leytonstone War Memorial Ward at the Walthamstow, Wanstead, and Leyton Children's and General Hospital. The two new wards will each contain 16 beds, and, in addition, on each of the two floors there will be four single wards for paying patients. Accommodation will also be provided for two resident house surgeons. The new additions will cost about £10,000.

## MOTORING NOTES.

### *Flexible Glass.*

ON Jan. 19th the *Motor* announced the invention of flexible glass, and in a later issue of the same journal some interesting facts about the discovery were disclosed. This "organic" glass is said to be a condensation product of formaldehyde and urea, similar to the imitation tortoise-shell of formaldehyde and phenol; many investigators had been trying to make it before 1920, when Drs. Fritz Pollak and Kurt Ripper, of Vienna, commenced their research work. They have overcome some formidable difficulties, especially in finding a way to keep flaws out of the larger pieces, but they now claim to have perfected a simple and sure method of making products "having the transparency of glass, resilient, insoluble to the highest degree, insensitive to differences in temperature, and adapted to be worked." The new glass is colourless, transparent, strong, and light; it is reasonably hard and so flexible that it will not splinter but fractures harmlessly. It is transparent to ultra-violet rays, can be coloured and etched, and its refractive index can be varied within certain limits. It requires little imagination to foresee some of the uses to which tough flexible glass could be put, not only in motor-car body-work but also in parts like petrol- and oil-tanks, where transparency would be extremely useful. It would minimise many of the risks of laboratory work and would take a heavy load off the mind of the practitioner, who often has to transport expensive and sometimes destructive fluids in a handbag. The inventors hope also to make lenses for giant telescopes far more cheaply than is possible with ordinary glass. We understand that arrangements have been made to market the glass in Great Britain, the interests of the proprietors in this country being represented by Mr. J. C. Vredenburg, 2–3, Charterhouse-square, London, E.C. 1, but we understand that no specimens of the glass are as yet available for inspection.

### *Current Prices of Second-hand Cars.*

Although everyone would sooner have a new car, not all can afford it, for the value of nearly all cars drops 25 per cent. in the first year. The price is a big one to pay for a depreciation in appearance that is often hardly noticeable, especially considering that when a good car is a year old it generally runs better than it did when new. It is therefore often worth while to consider buying a year-old car. The second-hand market is lower this year than it has been for a long time, and there are many firms, both in London and the provinces, who can be trusted to give what they advertise. Few good English cars lose mechanical condition after a year or less, but when examining a second-hand car it is as well to take a competent adviser to examine the state of the tyres and batteries. The Automobile Association assist their members in this way for a small fee. The doctor had better not buy anything sold before 1925 unless it is one of the few first-class makes.

Examples of current prices for last year's cars are: Austin 7 £105; Morris-Cowley two-seater £110, coupé £145; Clyno 11 occasional-four £125, four-seater £130; Standard 11·4 two-seater £125, saloon £180; Ariel 10 two-seater £145; Wolseley 11 two-seater £155, four-seater £175; Morris-Oxford four-seater £175, saloon £265; Bean 12 four-seater £220; Austin 12 four-seater with four-wheel brakes £265; Crossley 14 two-seater with four-wheel brakes £285; Alvis 12–50 four-seater £350; Bentley four-seater £795. A 1924 Daimler 16 saloon is advertised for £425 and a 1923 Bentley for £575.

These examples show an average of about 35 per cent. under the present new prices. Many dealers sell shop-soiled unused cars at 15 per cent. under their catalogue price. Intending purchasers should be quick about it, as the market rises with the spring demand.

### *The Problem of Dazzle.*

By inventing the electric self-starter the electrical engineers made motoring very much more comfortable in one way, but very much less in another, for the dazzle problem is undoubtedly a direct result of their ingenuity. A self-starter means a 12-volt battery, and a 12-volt battery is an irresistible temptation to makers to fit powerful headlights. If these were as efficient as the starter no harm would be done, but until the problem became acute it never occurred to any designer that something more was required from a lamp than just a more or less parallel beam. The ordinary headlight, as any night-driver can testify, sprays its light all over the road as well as directly in front of the car, and to meet a string of cars at night is one of the most terrifying experiences of motoring. The driver is completely blinded for several seconds, during which he may either run his car off the road or overtake and collide with an ill-lighted cart or unlighted bicycle. In self-defence he may hide behind a piece of tinted glass on the off-side of his screen or goggles, a shield of doubtful value. He can fit a spot-light on his near dumb-iron, set to light up the side of the road; this is an expensive fitting and does not protect him against obstacles on the road itself. What he does too often is to have as bright headlights as he can get and keep them on, and this, although it preserves him most of his view of the road, completes the vicious circle of the dazzle problem. Most motorists are considerate and would willingly mitigate their dazzle if they could do so safely, but so far hardly anyone has shown them how to. Dimming is appreciated by meeting traffic, but the dimmer runs a grave risk of failing to see an obstruction; it is therefore only a palliative. Besides this he is often too occupied to have any attention to spare for a dimming-switch. The problem of fog is allied to that of dazzle, and indeed a solution of one would solve the other. Tinted bulbs are of some use, but they again are only a palliative, for they cut off much light and so waste a great deal of current. The only remedy is to use a lamp which will throw a flat-topped beam, so that the light will not be reflected back from the fog to the driver's eyes.

Similarly, to avoid dazzle it is necessary to keep the beam down, so that its upper rays shall be below the eyes of other users of the road. The dipping head-lamp partly secures this result, especially if it is mounted high, but most makers fit their lamps too low. Even if the lamp is mounted in the right place, which should be just below the driver's line of sight, the ordinary head-lamp throws so much light above the main beam that it cannot be dipped far enough to provide safety for both parties. Besides this the process of dipping occupies one hand at a critical time. A lamp especially designed to throw a flat-topped beam is a better solution. The beam need not be a very narrow one, as if the top of the beam is below eye-level it does not matter to people in front where the light goes. At least one lamp on the market (the *Strange*) supplies such a beam. The top half of its reflector has a smaller radius than the lower half, and its screen has vertical ribs. Above four feet its beam is absolutely cut off, and one can walk straight up to it and stare at it without being dazzled. It gives a good driving beam, with diffused light at both sides and overhead. A French model is a lamp called the *Parallux*, in which the beam is held down by horizontal strips of yellow tape. It is said to be very good, but is not yet on the English market. Both these lamps cost no more than the ordinary first-class head-lamps. In the absence of a special device the least every car driver can do is to see that his own lamps are in proper focus and, if possible, that they are not pointing upwards. It is easy enough to focus head-lamps, and bad focus is responsible for a good deal of dazzle.

### *The New Clyno "13."*

The doctor wanting a low-priced car should examine the new 13 h.p. model made by Messrs. Clyno. For the price, £260, it is very good value. The steel body is well built, the cushions are comfortable, and covered with real leather. The side screens are rigid and neat in their thin steel frames, and a rear screen is part of the standard equipment. The floors have black druggets, besides a rubber covering. On the dashboard are a speedometer, clock, lamp, and "strangler" for starting; throttle and ignition controls are fitted on the steering-wheel and the gear and brake levers are on the right-hand side. The engine is not really a 13 but an 11 9, for its capacity is only 1500 c.cm. It is well designed, except that the magneto and carburettor are rather inaccessible; it would be an improvement to change the magneto and generator about, for the latter is mounted high up on the off-side and is very easy to get at. The brake adjustments are placed conveniently, and the tool-kit is adequate. The chassis is lubricated with a grease-gun in accordance with the latest practice. The driving position is comfortable, and the front seat will slide back far enough to give long legs plenty of room, but only, of course, at the expense of any passengers behind. Possibly a very tall driver might find that the gear-driven screen-wiper and the top rail of the screen got rather awkwardly in his line of sight, but a lesser man would drive comfortably enough. The hand-brake lever is a shade too near the side of the body, but might perhaps be bent inwards a little. The gear lever has a long travel and gives a comfortable and quiet change.

The new Clyno is a nice car to drive, as the engine is quiet and well behaved, the steering is extremely delicate, and the four-wheel brakes will work gently as well as pull the car up abruptly when really necessary.

The gear-box has only three speeds, and performance on middle is a little disappointing, this gear being far too low. It seems to be impracticable to balance mass-production engines so accurately that they will spin up to the top of their power-curve without complaining. The remedy is either to have four speeds with a fairly high third—and this is expensive—or to have an engine so large that it will take nearly everything on top, like an American car. The Clyno engine is not big enough for this. It is, however, an excellent car of its class, and may well become popular among medical men.

# BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Combating Venereal Diseases in Russia.*

AT a joint meeting of several Berlin medical societies Prof. Bronner, head of the venerological department of the Russian Commissariat for Health, recently described the campaign against venereal disease in Russia. In Moscow, he said, there is a central institute for the training of medical men as specialists. The course lasts a year and 600 medical men have already had instruction. At first a course of three to six months was the rule, but this proved too short. The times of attendance are early in the morning and late in the evening, so that workmen may have time to visit the institute without losing time at their work. The law allows only qualified medical men to attend patients, and quackery is nearly extinct in present-day Russia. Great stress is laid on the education of the public in hygiene. Persons suffering from venereal disease are advised to undergo treatment, but there is no regulation compelling them to do so. In the provinces there are similar institutes to the one at Moscow, and arrangements have been made to supply information to correspondents who lack the time to come themselves. Prostitution, says Prof Bronner, almost disappeared during the time when working was compulsory for everybody, but after the new economic policy was adopted prostitution began again, and is tolerated because the authorities consider that as long as they are unable to procure work for everyone, it would be wrong to hinder women from earning their living in any way they like. An energetic war is, however, being waged against brothels, and infected prostitutes are conveyed into a home called a prophylacterium, where they find not only medical attendance but also food and work. To inquire into the state of things in the country at large commissions of medical men with assistants have been sent out, and it has been ascertained that in some villages up to 45 per cent. of the population have venereal disease. In about 90 per cent. of these the infection is extragenital, and is due to the primitive housing accommodation and the deficient hygiene of the rural population. On an average in the provinces 1·5 to 4 per cent. suffer from syphilis, but in regions like Turkestan, with a native population, the percentage rises to 15 or 25, whilst amongst the Mongols of the Baikal provinces it is as high as 45. The reduction in the population of these tribes is ascribed in large measure to their being affected with venereal disease in a severe form. Prof. Bronner states that, whilst the cases of chancre are increasing, secondary syphilis, on the other hand, is diminishing, obviously owing to earlier treatment than formerly. In 1920 the amount of salvarsan produced in the Russian chemical factories was 65 kg . in 1925 the output had risen to 1800 kg., besides 100 kg. imported from abroad. Before it is dispensed to the public the drug is submitted to a thorough chemical and biological test. Prof. J. Jadassohn, the President of the Association for the Prevention of Venereal Diseases, stated at the meeting that in his visit to Russia he had gained a very good impression of the work done by the Russian Government. In Russia more than elsewhere the prevalence of syphilis was due to failure of personal hygiene. Similar conditions had existed in Germany during the war and shortly afterwards.

### *The late Prof. Israel.*

The death in Berlin on Feb. 20th of Prof. James Israel removes one of the most celebrated of German surgeons Born in 1848 in Berlin, he studied in the university there, and after qualification continued his medical training at Vienna, London, and Edinburgh. Returning to Berlin, he became assistant at the Jewish Hospital under Langenbeck, the surgeon, and Traube, the physician, and when fully equipped by all his experience was appointed chief surgeon to the Jewish Hospital, where he remained until his retirement in 1918. It was Israel who first described actinomycosis in men as early as 1878; former observers had not clearly understood its nature. His researches covered many branches of surgery, but his principal work concerned the kidneys, and in 1901 he published his standard treatise on renal disease from a surgical point of view. Only two years before his death he issued, in collaboration with his son, a new work on the diseases of the urogenital system. Amongst other things, he showed that removal of one kidney may prevent the spread of the disease to other organs. Prof. Israel was not a university lecturer, but trained a large number of assistants, of whom his successor at the Jewish Hospital, the late Prof. Karewski, may be mentioned as one. He had a very large international practice, and was frequently called into consultations abroad, on one occasion being called to St. Petersburg to see the Czarovitch, who was suffering from hæmaturia due to hæmophilia. He enjoyed special renown among the Jews of the East, who before the war used to flock to consult him, not only on surgical matters, but for many bodily and psychical ailments. He was a man of high culture and very representative. Although 78 years of age, he was engaged in practice until a few weeks before he died.

### *Financial Difficulties of German Universities.*

The number of German universities is undoubtedly much too large. Apart from the older ones, whose foundation partly dates back to the Middle Ages, there is a number of others recently established. Shortly before the war Frankfort was made the seat of a university which is not supported, like the others, entirely by the State, but largely out of municipal funds and by private endowment by the inhabitants of that once wealthy city. Even since the war new universities have been opened in Cologne and Hamburg, whilst the old university of Münster has been enlarged by the addition of a medical faculty. Düsseldorf has become the seat of an academy for post-graduate study, and it is intended to make this also into a university. It is characteristic that the new foundations are not, like the older ones, situated in medium-sized and small towns, but in large cities. Several of the smaller universities are said to be in financial difficulties, for the State cannot afford to give them adequate grants. This applies to the one at Giessen in Hesse, where the pharmaceutical institute has already been closed and amalgamated with a technical college at Darmstadt. It has been suggested, indeed, that the University of Giessen should be closed altogether, for others abound in the neighbourhood. The German universities, of course, vary greatly in size. Berlin is the largest, with 10,000 students; Munich has 7068; Cologne, 4609; Leipzig, 4400; Breslau, 4288; Bonn, 3209; Freiburg, 3020; Frankfort, 2635; Tübingen, 2533; Munster, 2531; Heidelberg, 2516; Göttingen, 2593; Halle, 2301; Marburg, 2156; Wurzburg, 2124; Hamburg, 2075; Jena, 2015; Königsberg, 1643; Kiel, 1601; Giessen, 1308; Erlangen, 1292; Greifswald, 917; and Rostock, 784. In those smaller towns where the economic prosperity of the population mainly depends on the undergraduates, the idea of abolishing the universities has created some anxiety, but so far the discussion has only been purely theoretical.

## BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

### *The Shortcomings of Private Practice.*

MEDICAL ethics are in the limelight just now. Allegations against a surgeon who refused to visit a patient as soon as he was called have recently been the pretext for a vicious outburst against doctors in a section of the daily press. Other journals have taken up the cudgels on behalf of the profession, against its gossiping detractors, but a certain amount of public dissatisfaction is evident. This makes a recent address given by Dr. János Sándor all the more topical in its interest. His subject was the cessation of private practice.

A change in the relations of doctors to the public and to each other, is, he considers, imminent. If the doctor is to be at the disposal of every sick man, giving to everyone the same unselfish service and the same knowledge and care, then the whole system of private practice must be abolished, and the sanitary service must be put into the hands of the State, which will supply its citizens with physicians, drugs, and surgical treatment, just as it supplies them with the machinery of the law. It may be argued that this would deprive patients of the right to choose their own medical advisers, said Dr. Sándor, but already most of the population have been deprived of this right. The peasants in the villages have only one doctor at their disposal; the workers in towns must attend those appointed by their assurance offices. As for sick clubs, Dr. Sándor remarked, the fees of the club doctor are so small that no physician can regard appointment to a club as his main vocation, and he is forced to put his heart mainly into his private practice—a fact very well known to his patients. It is notorious that the private doctor examines his cases, as a rule, much more conscientiously than does the badly paid club doctor. But if there were no paying and non-paying patients this abuse would cease.

It would not take long, Dr. Sándor considers, for people to get used to the fact that they could not choose their own doctor. If one of our forefathers of the eighteenth century were to rise from his grave he would undoubtedly consider it an unheard-of interference with his rights when he found that he could not build a house on his own ground without conforming to the municipal regulations about site, material, and construction. He would think it intolerable that he should not be allowed to drive his horses along the street at more than five miles an hour; that he must go to bed before 1 o'clock in the morning; that he should have to open and close his shop, fix the prices of his goods, cleanse his sidewalk, vaccinate his children, and do a hundred and one other things as the law prescribes. Though used to the abuses of absolutism in government, the visitor from the past would consider all this interference with his rights utterly preposterous, and would hurriedly return to the grave whence he came. Yet we consider these regulations reasonable; in the same way our descendants will learn to regard a nationalised health service as something natural. "We doctors," continued Dr. Sándor, "know perfectly well that the public is mainly incapable of using its right of free choice; as a rule it cannot accurately judge of the capabilities, knowledge, and conscientiousness of a doctor, and often it prefers the well-advertised man who talks a lot to the quiet man who is efficient. Experience shows that it is not the best doctor that has the biggest practice."

Public institutions maintained by the State are, he admitted, to a certain extent unpopular, and do not always deal uniformly and fairly with every citizen. Nevertheless this uniformity in treatment would in course of time become the tradition of a State medical service. Doctors, moreover, would be relieved of the cares of gaining a livelihood, for obviously the State would have to give them adequate remuneration and provide suitable pensions for old age or sickness. In some countries, he added, the medical service is already nationalised, to the complete satisfaction of both doctors and public.

The advantages of nationalisation would be many. "My idea," said Dr. Sándor, "is that every physician should have his own district with really well-equipped dispensaries for ambulant patients. Specialists and consultants could be summoned by the doctor in attendance or, in serious cases, by the patient himself. Night service would be organised in towns and cities." As things are at present the practitioner spends most of his time wearing out health, clothes, and boots by attending patients at opposite ends of a large district. If a postmaster handed a postman a bunch of unsorted letters to deliver in all parts of a big city he would be thought crazy; everyone finds it natural that a postman should have his designated streets. Why, then, should doctors alone have to fight against a lack of system in their work? Reorganisation would not benefit the doctor only; it would enable his patients to get him quicker in emergencies. Fewer doctors would be needed and the present regional disproportion could be adjusted. (In different parts of Roumania the number of doctors per 100,000 of inhabitants varies from 117 to 18.) The unfortunate economic situation in continental countries at present often prevents people incurring the expense of calling in a doctor till a disease is well advanced. With free medical treatment it would be otherwise.

It may be objected, said Dr. Sándor in conclusion, that the removal of personal profit as a motive and the cessation of competition would make for poorer work. Yet thousands of medical men spend years and years in clinics, hospitals, and laboratories, working hard for nominal salaries, and sacrificing their lives to science or charity. A perfect State system does not exclude the possibility of rising according to merit. Selection of doctors should begin in the university, and only those should enter the service who are led to it by a love of the medical vocation and have the needful moral and physical capacity. If doctors were not created haphazard there would be fewer problems in medical ethics. "It is my firm conviction," said Dr. Sándor, "that within a short time the whole of mankind will hold it most natural that just as every passer by can avail himself of the pavement and lighting of the street, so also everyone should have an equal right to free medical attention."

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Increase of Syphilis.*

Dr. Jeanselme, professor of syphilography in the Paris Faculty of Medicine, has recently remarked that the number of cases of fresh syphilitic infection presenting themselves at the Hôpital St. Louis has definitely increased during the past year. His colleagues have made the same observation, and it seems that the total number of patients with recent syphilis treated in the six dispensaries of the hospital has risen from 1055 in 1924 to 2445 in 1925—that is to say, there has been an increase of 20 per cent. The Hôpital St. Louis draws its patients from every quarter of the capital and its outskirts, and it is reasonable to conclude that syphilis is making definite headway at present amongst the working classes. A provincial inquiry suggests that this state of affairs is true of the rest of France also. Two reasons are put forward to explain the recrudescence. First of all there is the invasion of foreign immigrants. In one of the big manufacturing works on the outskirts of Paris there are over 10,000 foreigners, besides 2000 natives from the colonies, amongst the 30,000 employees—that is, nearly 30 per cent. of the total number are not French. Of 250 syphilitic patients in the Hôpital St. Louis, about one-fifth are foreigners or colonial natives; and really the proportion is higher than this suggests, because the males amongst them account for over 31 per cent. of the inmates of the male wards. Again, amongst 451 cases of recent syphilis treated at the dispensary in 1925, there were 260 French, 140 foreigners, and 51 North Africans. And the proportion of foreign patients is just as high in the other big industrial centres and ports as it is in Paris.

The second cause of the recrudescence of syphilis in France is undoubtedly the general use of bismuth just now, not only as a secondary treatment, but as the means of attack against the disease. This is due to the discredit into which the intravenous use of arsenobenzol has unfortunately and unjustifiably fallen.

### *Physicians' Compensation.*

An interesting case has just been decided by the Paris courts. A physician, summoned in an emergency by a friend of the patient, later presented a bill which the patient's family considered too large. On the refusal of the family to pay more than one-third of it, the physician attacked the friend who had summoned him. The courts held that to do so would only have been justifiable if the family had refused to make any payment whatever. As they had not done this the claim made against the intermediary was thrown out of court, and it was decided that the physician must still negotiate with the family.

### *Mechanical Milking.*

Dr. Henri de Rothschild, who for 18 months has been trying mechanical milking amongst some 80 dairy cows at his establishment at Vaux-de-Cernay, has recently given the Académie de Médecine an account of his experience. From the practical point of view there is economy of both time and labour, and neither filtering nor pasteurisation is needed after milking. The milk obtained mechanically keeps longer, especially in summer, and can be taken over long distances without there being any danger of it turning. From the scientific standpoint it cannot be regarded, strictly speaking, as aseptic, as has sometimes been claimed, and in spite of the most elaborate precautions it always contains a large number of organisms. But whereas a sample obtained in the usual way by hand and collected in ordinary receptacles washed out in cold water has about 270,000 colonies per c cm. after four days' incubation at 37° C., a sample from the machine shows not more than 30-70,000. The difference is considerable, and even if this milk cannot be called aseptic, it can at least be called clean.

### *Blood Transfusion in Infants.*

Dr. Guéniot, who has been studying blood transfusion as a treatment of debility in the new-born and in premature births, has found that the method is not without difficulty, and should be adopted only in cases not responding to the usual methods of care and feeding.

It has been pointed out that many laboratories in France are really incompetent to make the more complicated and delicate biological tests often required. The Académie de Médecine is heartily supporting a movement to institute rigid supervision of laboratories advertising publicly.

At the Faculté de Médecine Prof. Roussy has just closed a series of impressive conferences on cancer. The directors of cancer service at Marseilles and at the Curie Institute of Indo China have just been added to the committee appointed by the French Government in 1922 for coördinating methods of study and treatment.

Easter vacation courses from March 29th to April 10th are offered at the Faculté de Médecine. These include a course in criminology, to be given at the Palais de Justice, obstetrical courses, and a revision course on laboratory diagnosis at the Hôtel Dieu. A valuable course on occupational accidents is being continued by Balthazard, Lhermitte, Claude, Dervieux, Duvoir, Laignel-Lavastine, Terrien, and others. All sections of the subject are thus ably covered.

Prof. Thiery, well known for his surgical work in different hospitals at Paris, was on March 11th presented with a medal by his pupils, who wished thus to express their appreciation of his work and teaching.

## UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

### *The Control of Narcotics.*

THE federal control of narcotic drugs is exercised through the Harrison Act. The constitutional validity of this Act was challenged in 1919 and was upheld in the Supreme Court by a majority of only 5 to 4. A strong hint has now, however, been dropped by the Court that its decision might be reversed if the subject again came up for review. To understand the constitutional position it should be realised that the Federal Government can exercise only those powers which are specifically granted to it under the constitution. In the absence of definite instructions the right to legislate is presumed to lie with the State Government—a presumption exactly opposite to that which obtains under the Canadian constitution. The fathers who drew up the constitution of the United States foresaw a good deal, but some things they overlooked, and among them the growth of health legislation. There is no provision for control of health by the Federal Government. In passing laws under these limitations Congress has shown from time to time a good deal of ingenuity. Not having power to protect certain migratory birds, for example, it took advantage of its constitutional right to make treaties with foreign powers, and concluded a treaty with Canada in which the protection of certain birds was ensured on both sides of the frontier. In public health legislation advantage has constantly been taken of the right of Congress "to regulate commerce with foreign powers and among the several States." The Pure Food and Drugs Act is an example of successful legislation under this head.

The Harrison Narcotic Act depends on the right of Congress to raise taxes. Under the Act every physician who wishes to prescribe narcotics has to pay a tax—a tax which is held by many physicians to be quite unnecessarily severe, since the clear intention of the Act is not to raise revenue, but to control the distribution of certain drugs. The Child Labor Tax Law, approved in 1919, was found by the Supreme Court in 1922 to be unconstitutional, and the argument is of sufficient historical importance to be quoted at length:—

> "Taxes are occasionally imposed in the discretion of the legislature on proper subjects with the primary motive of obtaining revenue from them and with the incidental motive of discouraging them by making their continuance onerous. They do not lose their character as taxes because of the incidental motive. But there comes a time in the extension of the penalising features of the so-called tax when it loses its character as such and becomes a mere penalty with the characteristics of regulation and punishment. Such is the case in law before us."—*Child Labor Tax Case*, 259 U.S. 20, decided May 15th, 1922.

It will be seen that with this precedent another onslaught on the constitutionality of the Harrison Act is likely to prove successful. The *Journal of the American Medical Association* (Feb. 27th, 1926, p. 627), reviewing the situation, expresses no regret at the danger in which this Act is found. "No satisfactory evidence has yet been adduced," it remarks, "to show that the Harrison Narcotic Act has accomplished or is accomplishing its purpose, the suppression of the narcotic habit." Too little is known about the underground traffic, and apparent regulation by federal action may merely be blinding people to a serious state of affairs. An international conference on narcotic addiction is being planned with some energy and is to be held this summer in Philadelphia. No doubt the importance of international control of the sources of production will be taken up at this conference, but it is difficult to see any possibility of effective action without the close coöperation and machinery of the Health Section of the League of Nations.

### *Vital Statistics of New York State.*

The report on the vital statistics of New York State for 1925 shows a very satisfactory state of affairs. The Milbank Foundation is at present financing three health demonstrations in this State, and although it is not possible to estimate quantitatively the influence of these demonstrations, there can be no doubt that they have contributed to the success of the health department's work. The general death-rate (12·7 per 1000) has been lower only once—in 1921. Except for minor variations this rate has declined steadily since 1900, when it stood at 21·4. If the 1900 death-rate had prevailed last year there would have been 60,000 more deaths. The infant mortality is 68 per 1000 live births, and is the lowest on record. Among the causes of death tuberculosis (all forms) has dropped into fifth place with a rate of 90·9 per 100,000. It is exceeded by diseases of the cardio-vascular system, pneumonia, cancer, and external causes, whose importance is in the order named. The death-rate from alcoholism is 7·9, which is five times the rate from this cause in 1920.

---

**Royal Commission on Local Government.**—This Commission, of which Lord Onslow is chairman, will not begin before Whitsuntide to hear evidence on the relations between local sanitary authorities and their constitution, areas, and functions. The postponement is to give time to consider the proposals for Poor-law reform, which are under discussion between the Minister of Health and the local authorities.

**Complimentary Dinner to Prof. T. G. Moorhead.**—Prof. Moorhead was recently put to the trouble of defending an action for damages brought against him by a patient whom he had examined in the course of his duty as consulting physician to a suburban hospital in Dublin. The action was unsuccessful, none of the charges being established; but his professional brethren in Dublin have thought it a suitable opportunity to express their entire confidence in him and their sympathy with him in the annoyance to which he had been subjected. Accordingly a complimentary dinner was given to him last Saturday night in the dining hall of Trinity College, Dublin. The chair was taken by the Provost of Trinity College (Most Reverend Dr. J. H. Bernard), in his capacity as an Honorary Fellow of the Royal College of Physicians of Ireland, and some 120 hosts sat down to dinner. Only four or five laymen, personal friends of Dr. Moorhead, were present. The staff of every hospital in Dublin, general and special, was represented, and among those present were teachers from all the schools in Dublin. The gathering was a remarkable exhibition of respect and affection for Dr. Moorhead.

## THE CONSTITUTION AND DUTIES OF THE GENERAL MEDICAL COUNCIL.

*To the Editor of* The Lancet.

Sir,—The exposition of the functions of the General Medical Council given by its Registrar in The Lancet of Feb. 6th clearly indicates the prime services it renders. In his words the two prime services are *first*, to prevent the unfit (in education and training) from gaining access to the Register, and *secondly*, to remove the unworthy from it. The Council is the sole arbiter in each situation, but its action is subject to the ruling of the Privy Council.

### *Evolution of the Council.*

When the Council came into being in 1858 it found the entry into the medical profession was by means of training under an apprenticeship system supplemented by education tested by examination under the control of the medical corporations and the universities. The supplementary education was entirely in the hands of the different educational bodies and in consequence it varied with each. The result was that the value of the diplomas granted and the degrees conferred also varied, a high standard being maintained at some places and a low one reached at others. The difference between the education given at the universities and that at the medical schools lay mainly in the scope and in the inclusion at the universities of a greater number of the subjects upon which the science and art of medicine are based.

The Council soon standardised the examinations, and after a time widened the scope of medical education in those medical schools and universities which were below the level of the best. While the Council was standardising the medical examinations it at the same time created uniformity in medical education. All the schools came to imitate one another, and to-day, it may be said, variety has been replaced by dull uniformity. The education of the doctor was improved by standardisation of the examinations, but education tends to deteriorate under the dead weight of uniformity established by insistence on stereotyped curricula. Variety is needed to-day to give elasticity once more to the education, and to afford each centre scope to grow in directions favourable to the widening of the outlook of the doctor. It matters not in the least that the doctor is better educated at one school in chemistry, at another in physics; but it does matter that he gets a wide, if not a particular, education in each subject so that he may in practice be able to apply his intelligence and make good use of principles. Again, it is of no consequence if he is unacquainted with minute details in anatomy and physiology, provided he shall have sufficient education in each of them to be able to turn to his knowledge of them for fundamental information when in difficulties.

In all the subjects, which form the basis upon which medicine rests, the Council need not now, so it appears to me, interfere with the medical schools, whether of universities or constituent colleges of universities; and it would be well to leave the education and the choice of those subjects entirely in their hands provided the standard attained at their examinations is such as to warrant the Council in accepting a certificate that the student is fit to enter upon his clinical and other studies. In that way freedom in the choice of subjects and in the scope of education would be restored to the medical schools, the beneficial effects of which, would, I believe, be very great.

If it be advisable for the Council to accept degrees from universities as evidence of sufficient education to entitle a graduate to enter upon clinical studies, it is still more advisable that the Council should exercise greater control over the education and training at the hospitals. The hospital is the clinical laboratory in which there is room and facilities for teaching a definite number of students and no more. At first the Council was content with declaring that a hospital with less than 150 beds would not be recognised as constituting a medical school, and so far as I am aware it still remains content. When that condition was laid down the trained apprentice entered the hospital and, as was said, he *walked* it, gathering as much information as he could and attending a few lectures while preparing himself for the examinations of the medical corporations and may be those of the universities. To-day the original condition needs supplementing in the direction of limiting the number of pupils that can be adequately trained in each hospital recognised as a medical school. That is essential in the interests of clinical training, as in those of the State and of the public The Council has power to effect this reform which has been too long delayed. The examinations may be good enough but the training is not, and the remedy should be applied without hesitation.

The Council as at present constituted is hardly fit for such work, for the great majority of those upon it represent the interests of teaching bodies. And representatives of the teaching bodies could hardly function as a composite authority for establishing changes in the existing system, and at the same time act as judge of what is best in the interests of all concerned.

### *The Present Position of Specialism; Technical Assistants.*

What the Medical Act did for the doctor it should now do for the specialist. It gave the doctor a position of privilege in the State, a position that membership of a corporate body is unable to bestow. Just as the member of a medical corporation was adequately educated, trained, and tested prior to 1858, so is the specialist of to-day, generally speaking, adequately educated but chiefly self-trained. The Council has insisted on education and training, and laid down a standard of attainment for the *legally qualified* practitioner. To-day the same should be laid down for all specialisms which are, of course, attainments after registration as it is now conducted. The Council needs the advice of the specialists to formulate a scheme for the education, training, and examining of specialists who desire to become recognised as such by the State. In the interests of medicine no less than that of the public this reform should be undertaken.

Before the final extinction of the apprenticeship system in medicine the apprentices served in the capacity of technical assistants. After its disappearance those who failed to qualify became assistants to a doctor. This was disapproved of by the Council as it led to the great evil of covering—which amounted to using the assistant to do the work of visiting and prescribing for patients under the cloak of his employer. The action of the Council in suppressing covering was correct and imperative. But unfortunately no steps had previously been taken by the doctors to develop the technical side of their work, which always had been, and is to-day, delegated to those who have no intention of qualifying themselves as doctors. It is, I believe, the duty of the Council to take this matter up and to regularise the practice, for it is one that is a necessary adjunct to general practice in whatever direction it may develop. The dispenser, the electrician, the masseur, the manipulator, and so on, are indeed essential portions of the complex medical machine Each to-day can be trained in his special work, and there can be no question as to the fitness of those technical assistants to share the advantages accruing from State registration. They are worthy of it and, if such be granted to them, medicine will gain, the doctors will utilise them to the advantage of their patients, and the public will benefit.

### *The Exercise of Judicial Powers.*

Just as the Council is paramount in determining the standard of education and training to be attained by a doctor prior to his registration for the enjoyment of certain privileges, so it is paramount in giving a decision as to whether a registered person, on complaints being made, is guilty of *infamous conduct in any professional respect.* Conviction is followed by the erasure of the name. There appears to be great confusion on the question of the power of the Council. In its proper capacity it acts as a court presided over by a judge assisted by a jury. It inquires, it interprets the meaning of the phrase "infamous conduct in any professional respect," it decides on guilty or not guilty; but the punishment to be awarded is not modifiable by the Council. That it has power to investigate, to judge, and to convict is indisputable. While it possesses such powers it can exercise no disciplinary control over the accused or the body of men registered. In this respect it is like a court of law in which conviction of an offence is dealt with, but in which no cognisance can be taken of the discipline of the people.

The medical profession is peculiar in that it possesses no statutory body in control of its discipline. It is true each medical corporation possesses such power over its diplomates and licentiates, but unless the registered doctor is a member of one of these corporations he is under no such control. A graduate of the older universities is uncontrolled and rightly so, for a degree is a mark of educational attainments which conduct of any kind cannot deprive a man of. A graduate of the newer universities may, however, be deprived of his degree on grounds of moral behaviour, but cannot be on professional grounds of any degree of gravity unless he be convicted in the courts of crime.

The General Medical Council is then not a disciplinary body for controlling the professional behaviour of the doctors who, if they do not belong to a medical corporation, are not under any authoritative body One may be needed.

### *A Suggestion for Reconstruction.*

When the Council was originally formed the members were representatives of the Crown, of the universities, and of the medical corporations, the two latter being statutory bodies. Direct representatives of the registered have been added. Owing to the establishment of a number of new universities the representation from them and from the medical corporations far outweighs the others; and now we have the proportion of 27 to 11 only for the Crown and the registered. In 1858 the principle adopted in the construction of the Council served, because the medical profession had not then emerged from the state it had reached in its development by the end of the eighteenth century. And the men appointed on the Council were true representatives of the doctors throughout the land, for each had passed through the only avenue into it—namely, through a period of an apprenticeship. To-day, matters are very different, for, it may almost be said, the members of the Council, with few exceptions, have never done any general practice nor, indeed, have ever had the opportunity of becoming acquainted with its needs and its intricacies. Therefore the Council, as it exists to-day, gives a preponderating influence to the teaching and examining bodies which under the present system are sole judges of their own work. This is a serious defect not only from the point of view of control to be exercised by the Council over teaching and the standard of examination, but also from that of the exercise of judicial powers; the consequence being that those who are unacquainted with the work of an accused, if he be a general practitioner, are constituted a court with judicial powers for the conduct of his trial and for pronouncing that he is either guilty or not guilty.

Such changes have occurred during the last three-quarters of a century that there is now a real need for the formulation of a new principle as a basis for the representation on the Council. The first function of the General Medical Council concerns education and the maintenance of a reasonable standard at the examination tests, but surely there is no need to have every medical educational body represented. There is, however, need for representation of the teachers in different clinical schools, of the registered in general, and of all specialisms, and of the technical assistants, if they become registered, and of the public through the Crown as at present. In respect to the second function, the removal of the unfit from the Register, the old principle should be applied in these matters—namely, trial by our peers. For this purpose it would, it seems to me, be best to obtain power for the creation of a panel representative of all the registered, from which a jury of 12 could be chosen on each occasion when persons were accused and a prima facie case against them established; say, by a small committee of the Council itself. Such a reform in representation would bring the Council up to date and would create confidence in its deliberations and in its decisions.

To meet the requirements of to-day the following reforms are indicated: (1) The registration of medical students to begin on entry upon hospital work. (2) The number of pupils at each hospital to be regulated in accordance with the facilities and opportunities existing in them for teaching, training, and giving responsible practice to every pupil. (3) The registration of all specialists under their different specialisms. (4) The registration of all technical assistants under the various sections. (5) Lastly, the reorganisation of the method of dealing with those registered as legally qualified practitioners accused of infamous conduct in any professional respect.

I am, Sir, yours faithfully,
JOSEPH GRIFFITHS.

St. Peter's-terrace, Cambridge, March 12th, 1926.

## THE TREATMENT OF POST-MORTEM INFECTIONS.

*To the Editor of* THE LANCET.

SIR,—Mr. Handfield-Jones is to be congratulated on the able manner in which he has dealt with this subject in your issue of March 13th. As you remark in your annotation the number of fatal cases is not large, but there are other less severe cases not reported, and the timely warning of the possible ill-effects of post-mortem injuries is most opportune. Although the bulk of post-mortem work is done at the large hospitals by experienced pathologists and assistants, many autopsies are performed, as you point out, by medical men in general practice, and Mr. Handfield-Jones's article will be of especial value to them. The article is a mine of valuable information and advice, and I hope it will be possible to reproduce it in pamphlet form and to broadcast it throughout the profession. It is worthy, too, of a prominent place in text-books of surgery and in works dealing with post-mortem examinations.

Like many other pathologists, I have on occasion passed an uneasy day after receiving a slight cut or scratch while making a post-mortem examination on a septic case or investigating a specimen from the operating theatre. Mr. Handfield-Jones deals with every variety of injury and its appropriate treatment, but I should like to lay stress on one or two of his points. The two directions, (1) cease work at once and (2) encourage bleeding, should be printed in large coloured type and hung up where pathologists work. To my mind the whole success of the prophylactic treatment depends upon the prompt cessation of work and thorough washing out of the wound by the patient's own blood. The least delay or insufficient bleeding is likely to counteract all the benefit to be obtained by this treatment.

The following is my own practice:

1. Directly a prick with a needle or scalpel is received, cease work and treat the wound, for it must be assumed that micro-organisms have been carried into the tissues.

2. Make the wound bleed under a stream of water, warm for choice but not hot. Keep this up until a fair amount of blood has been ejected, the bleeding being helped by repeated squeezing of the tissues well away from the wound. When it is considered that sufficient blood has been squeezed out of the wound to carry off any organisms that may have been *lying in its depths*—

3. Carefully cleanse the surrounding skin, usually by means of a brush kept permanently in a dish of 1/20 carbolic lotion. Great care must be taken not to scrub the wound itself for fear of dislodging organisms from the surrounding skin and rubbing them into the cut or prick.

4. Paint the wound over with iodine solution followed by a layer of "new skin" or collodion and a little cotton-wool.

Do not on any account use any antiseptic before making the wound bleed. The sealing up of a wound as advocated here applies, of course, only to the *very small* cuts and pricks which form the great majority of these post-mortem injuries. I am aware of the danger of sealing up a wound in this manner, but do it deliberately in the belief that all organisms have been ejected in the blood squeezed from the wound.

The foundation for the above method of treatment is based on the following considerations:

(*a*) Micro-organisms (say streptococci) are carried by the scalpel or needle into a slit in the tissues below the protective squamous layer of the skin.

(*b*) Bleeding occurs into this slit and the formation of a blood clot quickly occurs.

(*c*) When the clot forms it seals up the outlet of the wound and so effectually imprisons any organisms that may be lying in its depths.

(*d*) If the organisms are not destroyed by the body fluids they are free to multiply and disseminate into the tissues and blood stream.

These considerations justify the conclusions that—

(*a*) Immediate ejection of the organisms is necessary.

(*b*) Delay until a clot has formed renders it very difficult and perhaps impossible for this ejection to be successfully carried out.

(*c*) Scrubbing the wound is likely to push organisms into its depths.

(*d*) Antiseptics can only destroy organisms at the surface.

(*e*) Antiseptics, such as compounds of mercury and methylated spirit, cause clotting of albumin and so effectually seal up the mouth of a wound.

One illustration of the lack of knowledge possessed on this subject must suffice. A recently qualified man was asked what steps he would take in the event of receiving a prick while doing a post-mortem. He replied: "Rinse the finger in an antiseptic at the conclusion of the post-mortem." Mr. Handfield-Jones's remark about members of the honorary staff in a hurry is much to the point. The older pathologist will not be perturbed or deviated from his routine in the event of receiving an injury. But the young pathologist or clerk is apt to take his chance and get on with his work so that a great man may not be kept waiting.

I am, Sir, yours faithfully,
ERNEST H. SHAW.

Royal Northern Hospital, March 15th, 1926.

*To the Editor of* THE LANCET.

SIR,—In his useful and timely article Mr. Handfield-Jones strongly recommends a bath of tincture of iodine. I have no doubt of the usefulness of iodine in cases of ringworm, for the treatment of which I have never required to use any other drug during my experience of nearly 40 years, but as an antiseptic in other cases I have never been sure of its usefulness. In ordinary boils I have found it delay progress, but I have never known it cure the disease. In pyorrhœa I have used it freely, working it into the pockets around the teeth, and I have held the *liniment* in my mouth for three to four minutes without improving matters in the least. About six months ago I had to treat a very severe case of erysipelas in an otherwise apparently healthy young man. The disease began, as it frequently does, over the nose and spread over head, neck, and back down to and just over the femoral trochanters. It recurred four times in spite of vaccines, and serum injected intravenously and intramuscularly, and in spite of local applications of magnesium sulphate, buttermilk, and iodine. During its spread down the back I painted three inches of the spreading margin and four inches of the skin beyond this with the tinct. iodi. fort. until the skin was almost black, yet in six hours the disease had passed through the iodine-painted skin with undiminished strength. My faith in iodine as an antiseptic has been badly shaken.

I am, Sir, yours faithfully,

W. R. DAVISON.

Ballymena, March 13th, 1926.

## TREATMENT IN DISEASES OF THE NERVOUS SYSTEM.

*To the Editor of* THE LANCET.

SIR,—Sir James Barr's criticism of my first Lettsomian lecture only tempts me to ask one question. Which should be taken the more seriously? My remark that "If all the current wasted in a year on the limbs of hemiplegic patients could be stored in accumulators, the Prime Minister's scheme for supplying electricity to the country would be rendered superfluous," or Sir James Barr's views on the pathogenesis and treatment of acute poliomyelitis and progressive muscular atrophy, which he quotes from an address he gave in 1924. He is kind enough to say that my lecture is transparently honest. May I reciprocate by saying that no one will doubt his statement that he "has dabbled a little in nervous diseases."

I am, Sir, yours faithfully,

E. FARQUHAR BUZZARD.

Wimpole-street, W., March 15th, 1926.

## GARDENLESS CITIES.

*To the Editor of* THE LANCET.

SIR,—Overcrowding in large towns can be remedied in two ways—by migration to the country, or by building lofty blocks of tenements.

As to migration, the London County Council is building at Morden, in Surrey, on an estate of 850 acres, a town of 8000 houses for 40,000 inhabitants. Now the usual size of an allotment garden is a sixteenth of an acre, and it is said it ought to be double that; but at Morden it would not be possible to have adjacent to the house a garden of sufficient size for the tenant to grow his own vegetables—he can have only a backyard.

As to tenement blocks, they should not be condemned offhand as vertical slums. A slum is a collection of houses once new and clean, which have been allowed to become overcrowded and dirty. In tenement blocks overcrowding would be prevented, and the owners would be responsible for the cleansing of the lifts and emergency stairs, which they would carry out with the most approved electrical appliances; if this service were extended to the rooms, much waste of labour in out-of-date methods would be saved; hot water could be supplied from central furnaces; open-air schools established on the flat roofs; and in the basement baths of warm water and ultra-violet light provided. On the ground floor there might be a restaurant with a store for the sale of food. No doubt there might be a greater risk among the children of epidemic disease, which in its turn might prepare the soil for other diseases, but there is no need to speculate as to whether it is possible to bring up children properly in the centre of a large city—the experiment has been tried. The Foundling Hospital was moved to its present site in 1745, and ever since then children have been brought up there in accordance with the knowledge of the day, with what results the records will show. Now another experiment is to be tried: the children are to be moved into the country, but on to what soil and into what type of building we have not yet been told.

I am, Sir, yours faithfully,

WALTER EDMUNDS.

Putney, S.W., March 13th, 1926.

# Obituary.

## WILLIAM PERMEWAN, M.D. LOND., F.R.C.S. ENG., J.P.

BY the death of Dr. W. Permewan on March 9th, at the age of 61, the medical profession has lost a member who distinguished himself in many departments of life.

William Permewan came of a Cornish family, and was educated at University College, London, where he graduated in medicine in 1886. After holding an appointment as surgeon to the Miners' Hospital, Redruth, he went to Liverpool as house surgeon to the David Lewis Northern Hospital. Taking his M.D. in 1888, he became F.R.C.S. in the following year, and in 1892 took the D.P.H. at Cambridge. It was at this time he began to interest himself in laryngology, and afterwards he became aural surgeon to the Royal Southern Hospital and the Southport Infirmary, and in 1914 lecturer in laryngology in the University of Liverpool. Dr. Permewan contributed numerous articles on diseases of the throat, nose and ear to medical journals, and was a vice-president of the Liverpool Medical Institution. In his own city, however, he was perhaps best known for his interest in politics and municipal affairs. From 1901–07 he represented Abercromby ward on the City Council and served on several of the council's committees. In 1910 he fought one of the keenest political battles in the history of Liverpool against Mr. F. E. Smith (now Lord Birkenhead), who was standing in the Unionist interest. Dr. Permewan was then a Liberal and Home Ruler and wrote a good deal on political subjects. His articles in the *Fortnightly Review* attracted attention, and in his political contributions he was unusually accurate in gauging the trend of public opinion, though in his two attempts to enter the House of Commons he was unfortunate in the selection of a constituency. Of late years he came to the conclusion that a strong Conservative Government was needed to counteract the Socialist tendencies of the day, and he played a prominent part on the Conservative side in recent elections.

"Dr Permewan," writes Sir James Barr, who has sent us many intimate details of his friend's life, "was a brilliant conversationalist, an excellent debater, and a man of great literary talent. He had a splendid voice, and if he had taken up music as a profession he might easily have been a distinguished operatic singer; his vocal power and manner would soon have placed him in the front rank."

During the war Dr. Permewan was attached to the 1st Western General Hospital. In 1901 he married a sister of Sir Max Muspratt, and the sympathy felt by his friends for his widow and son is greatly deepened by the fact that his brilliant daughter died of appendicitis only seven weeks before him. Dr. Permewan's funeral on March 13th was attended by a large and representative gathering of his fellow-citizens, including Lord Mayor, magistrates and aldermen, and the Vice-Chancellor of the University.

THE LATE DR. O'DONNELL.—Dr. David O'Donnell, who died on Feb. 25th at his home at Goole at the age of 55, had one of the largest panel practices in the West Riding. Born at Waterford, he was educated at Queen's College, Cork, and at Dublin, graduating in medicine at the University in 1891 Over 30 years ago he went to Goole, since when he has been identified with many of the social and religious activities of the town. He leaves a widow, three daughters, and one son, who is a medical student.

THE LATE DR. J. S. HENDRIE.—Dr. John Stewart Hendrie, who was killed in a road accident at Bearpark on March 8th, had recently gone to Bearpark as assistant to Dr. John Brown. At the time of the accident he was on his way to see a patient in response to an urgent call, when his motor-cycle collided with a lorry. Dr. Hendrie, who was only 23 years of age, was a native of Ayrshire and graduated at the University of Edinburgh last year.

# Medical News.

Royal College of Surgeons of England.—At an ordinary meeting of the Council on March 11th, Sir John Bland-Sutton, the President, in the chair, Sir Cuthbert Wallace (St. Thomas's Hospital) was elected Vice-President in the vacancy occasioned by the resignation of Mr. James Sherren. Mr. Gwynne Williams (University College Hospital) was elected a member of the Court of Examiners in the vacancy occasioned by the resignation of Mr. Raymond Johnson. Sir Cuthbert Wallace was also elected representative of the College on the Senate of the University of London. Dr. W. S. A. Griffith was reappointed a representative of the College on the Central Midwives Board. The President was appointed a representative of the College to attend a meeting of the Royal Society on April 30th in connexion with the celebration of the Lister Centenary. Mr. F. J. Steward was elected a member of the Committee of Management of the Examining Board in England.—The President reported that a bust by Nollekens of Dr. Matthew Baillie, and a bust by Chantrey of William Hunter Baillie had been presented to the College by Miss Hunter Baillie. She has also given five volumes containing all the records in her possession relating to the Hunter Baillie family, with annotations by herself and others. The compilation has been the work of many years, and has been throughout a labour of love. In her eighty-third year she gives them to the College "with the sure hope that the profession with which I have had such near connexion will go on from strength to strength." The best thanks of the Council were given to Miss Hunter Baillie for her very interesting and valuable gifts.

The diploma of Fellow was conferred upon David Levi, St. Mary's Hospital, who has now attained the requisite age.

Diplomas in Tropical Medicine and Hygiene were conferred (in conjunction with the Royal College of Physicians of London) upon the following candidates from the London School of Hygiene and Tropical Medicine :—

A. K. Abdel-Khalik, M. A. H. Atiya, B. N. V. Bailey, H. L. Batra, H. B. Boucher, Gwendolen S. M. Chataway, E. E. Claxton, A. K. H. El Shurbagi, S. C. Gomes, G. D. Gordon, F. G. Greenwood, J. R. Hayman, Margaret Holliday, Laura M. Jacobs, J. J. Keevil, H. D. B. Miller, R. M. Morris, E. A. Penny, J. C. Pyper, R. D. Reid, E. A. Struthers, A. G. Taylor, L. G. W. Urich, W. J. Webster, Isabel J. Woodhouse, L. T. Yiu, and W. A. Young.

Licences to practise dentistry were conferred upon the following 50 candidates :—

C. E. S. Abraham, Univ. Coll. ; E. Baines, Birmingham ; J. A. Becker, E. Boyd, D. M. Calder, J. D. Cambrook, and J. Chamberlain, Guy's ; H. Christopher, Royal Dental ; A. Clements, London ; J. C. Curphey, Royal Dental ; H. J. Daneel, A. A. Danino, and L. R. Davey, Guy's ; Marjorie H. Davy, Royal Dental ; S. Droomer, H. E. Edney, T. G. Edwards, A. E. Farara, and W. G. Fenn, Guy's ; H. Greenberg, Royal Dental ; K. H. Greenwood and H. Hall, Guy's ; L. J. Hardy, London ; A. G. Hegnauer, Royal Dental ; W. Hops, Guy's ; A. Jacobs, Bristol ; A. A. Jones, Royal Dental ; J. P. Lambert, London ; K. E. Lawton, Paris ; W. Lee, Manchester and Royal Dental ; H. F. Leese, Liverpool ; C. F. Linthwaite, Univ. Coll. ; F. D. Manners, Guy's ; E. W. Marthews, Univ. Coll. ; M. L. Myerson, London ; T. T. Oliver and C. E. Pedley, Guy's ; C. F. Preston and J. D. Robson, Royal Dental ; I. S. Rutter, F. W. Sander, E. N. Screech, and A. G. Taylor, Guy's ; H. C. Thomas, Univ. Coll. ; C. H. Tisdall, Royal Dental ; A. E. Treweek, L. Walters, and F. S. Warner, Guy's ; J. W. White, London ; and W. G. Williams, Royal Dental.

Fellowship of Medicine and Post-Graduate Medical Association.—Mr. A. Tudor Edwards will give a demonstration in clinical surgery at the Westminster Hospital on Wednesday, March 31st, at 2 P.M. This demonstration will be free to members and to ticket holders for the Fellowship's general course. Beginning on April 12th, St. Peter's Hospital will hold a two weeks' course in genito-urinary diseases. There will be clinical sessions daily, followed by formal lectures every afternoon (including Saturdays) by members of the staff. The National Orthopædic Hospital has also arranged a comprehensive special course from April 12th to 24th, for which the fee is fixed at £2 2s. From April 14th to May 5th Dr. Heald has organised a series of lecture-demonstrations in electrotherapy at the Royal Free Hospital at 5.15 P.M. An intensive course in proctology is available at St. Mark's Hospital from April 19th to 24th. There will be daily sessions from 10 or 10.30 A.M. until 6 P.M., including Saturday. Instruction will be by lecture, by demonstration, and by operative demonstration. The course will only be held if 10 entries are received by April 12th. Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Sir Arthur Keith is to be nominated as President of the British Association when it meets at Leeds in 1927.

University of London.—The title of Professor of Physiology in the University has been conferred, as from March 1st, 1926, on Dr. J. S. Edkins, in respect of the post held by him at Bedford College. He was made reader in physiology in 1915. During the war Prof. Edkins was a member of the Physiology Committee of the Royal Society and of the Grain Pest Committee, and also acted as secretary of the Chemical Warfare Medical Committee (a joint committee of the War Office and the Medical Research Council)

University of Oxford.—The next award for the Radcliffe Prize will be in 1927. This prize of £50 is awarded by the Master and Fellows of University College every second year for research in any branch of medical science, and is open to all graduates of the University who have proceeded, or are proceeding, to a medical degree in the University, and passed the last examination for the B.A. degree not more than 12 years ago, and are not Fellows on the Foundation of Dr. John Radcliffe. Memoirs must be received by the Secretary of Faculties, at the University Registry, on or before Dec. 1st, 1926. No memoir for which any University Prize has already been awarded is admitted to competition.

Early Mental Illness: Conference at Warwick.—At the instance of the visiting committee of the Warwickshire Mental Hospital at Halton, a conference has been held at Warwick of representatives of the more important general hospitals in the county to discuss the question of out-patient treatment for cases of early mental illness. Dr. C. H. Bond, of the Board of Control, said that this was the first conference of the kind and hoped that it would result in the general hospitals providing timely treatment in their out-patients' departments. A resolution was eventually passed urging the desirability of such a course

Medical Congresses in Russia.—The Commissariat of Public Health has organised a series of All Union congresses on the following subjects : Tuberculosis (April), Ophthalmology (May), Sanitary Inspection of Railways and Water Transport (May), Bacteriology and Epidemiology (May), Plague (August), Gynæcology and Midwifery (May), Therapeutics (second half of May). All these congresses will be held at Moscow except the one on gynæcology, which will be held at Leningrad. We are informed by the London representative of the Red Cross Society of Russia (U.S.S.R.) that medical guests from abroad have been made heartily welcome at medical conferences in Russia. The Commissariat of Public Health generally assists scientific visitors to obtain visas from the Foreign Office. Medical men wishing to attend will be given every help if they apply to Dr. V. N. Polovtsev, Russian Red Cross, 150, Southampton-row, London, W.C. 1, who states that "it is the sincere desire of our medical circles to come into friendly touch and coöperation with their British colleagues."

Medical Insurance Agency.—At a meeting of the committee of management held recently at the house of the British Medical Association, the following regulations were adopted for the administration of the Educational Grants (Girls) Fund :—

(a) It is not at the moment within the bounds of practical politics for the Agency to endeavour to establish a school for girls on the lines of Epsom College for boys, nor are the Committee convinced of the desirability of such a step.

(b) It is desirable that the Agency should take over and make itself responsible for the cost of education, with the contingent maintenance, where necessary, of approved girls (daughters of deceased or disabled medical men or women) between the ages of 10 and 18 should it be considered advantageous to continue education and/or maintenance up to the latter age.

(c) The usual method of selection will be for the Royal Medical Benevolent Fund Guild to be asked to submit names and particulars of suitable candidates and schools. The choice will be made by the subcommittee.

(d) In the first place three girls will be selected, the responsibility for others being assumed as and when the funds at the disposal of the subcommittee permit. It is estimated that an average sum of £100 per annum will be sufficient for each case.

(e) The foregoing shall not exclude the possibility of the subcommittee rendering assistance in cases of deserving and urgent emergency at more mature ages.

(f) Reports as to the progress of girls whose education has been undertaken by the Medical Insurance Agency will be made to the Royal Medical Benevolent Fund Guild and produced to the subcommittee.

(g) The Agency will be at liberty to terminate its liability should altered circumstances render in its opinion the assistance it gives no longer necessary or useful.

(h) The Agency may also withdraw its support after giving one term's notice of its withdrawal should it consider the work or conduct of any scholar to be unsatisfactory.

The Agency then resolved to undertake forthwith the cost of education, with the necessary maintenance, of three selected girls, the claims for selection being considered at length.

**Royal Society of Medicine.**—The Society's house and library will be closed from Thursday, April 1st, to Tuesday, April 6th, inclusive.

**Tuberculosis Society.**—A meeting will be held on Friday, March 19th, at 1, Upper Montague-street, Russell-square, London, W.C., at 8 P.M., when Dr. A. E. Evans, Inspector, Board of Control, will read a paper on Tuberculosis in Mental Hospitals.

**Hunterian Society.**—A dinner meeting of this society will be held at Simpson's Restaurant, 2, Bird-in-Hand Court, 77, Poultry, Cheapside, London, on Monday, March 22nd, at 7.30 P.M. About 8.30 P.M. a discussion on Sterilisation of the Mentally Unfit will be opened by Dr. R. A. Gibbons, Mr. Harold Cox, and Dr. R. Worth.

**Conference on Tuberculosis.**—As announced in our issue of March 6th, a joint provincial meeting of the Tuberculosis Society and the Society of Superintendents of Tuberculosis Institutions is to be held at Cambridge from March 25th to 27th. Information may be had from Dr. F. J. Blackmore, Tuberculosis Dispensary, Maxey-road, Plumstead, London, S.E. 18.

**Röntgen Society.**—The ninth Silvanus Thompson Memorial Lecture will be delivered by Sir John Thomson-Walker in the Barnes Hall, Royal Society of Medicine, 1, Wimpole-street, London, W., on Tuesday, March 30th, at 8.15 P.M. His subject will be Radiology in Urinary Surgery.

**Medical Society of London.**—The annual dinner was held at the Grand Hotel, Trafalgar-square, London, on March 12th, with Sir Holburt Waring, the President, in the chair. The first of a series of admirable speeches was delivered by Sir Archibald Garrod, who proposed the toast of the Medical Society of London, and alluded to the fact that his father, Sir Alfred Garrod, had been its president in 1860. In those days Harley-street had been very different. Then only 24 doctors were in practice there—and they all lived in their own houses. He congratulated the Society on having retained its independence when most of the other medical societies of London were united in the Royal Society of Medicine. The Society's special merit was that it was not divided into sections, and all branches of the profession could meet to discuss the same subject. Replying to the toast, Sir Holburt Waring cordially agreed with this view. The Society, he considered, brought the general practitioner and the consultant on to common ground. Speaking of its future, he said that, unfortunately, the lease of the buildings in Chandos-street would come to an end in about 16 years, and although the Society's financial position was excellent, it seemed unlikely that the conditions imposed by the ground landlord could be accepted as they stood at present. Sir Holburt Waring dealt amusingly with the contention that Harley-street had only recently become overcrowded. In the house where he started practice, he said, there had been a nursing home in the roof and a veterinary hospital in the basement, besides numerous consultants all the way up the stairs.—Mr. Warren Low, proposing the toast of the Guests, said that when asked to do so he was reminded of the octogenarian who was sentenced to 15 years' imprisonment. "My Lord," said he, "I should never live to do it." "Never mind," said the judge, "do as much as you can." He considered that the Society should follow the maxim of John Lettsom, its founder: *Facta non verba* (which an American had translated as "Plenty of victuals and no speeches"). Mr. Low at first had wondered what Dr. Lettsom, as a strict Quaker, would have thought of the Society entertaining the head of the Army Medical Services. Then he had remembered that Dr. Lettsom—Quaker or no—had allowed himself to be gazetted as Physician to the Camberwell Volunteer Infantry! The country, Mr. Low continued, was very fortunate in having Sir William Leishman in control of its military medical service, for he demonstrated in person that a man of science could rise to the highest place in that service as an administrator. Speaking of the Regius professors, Mr. Low hoped that some day the older universities might recognise surgery, the shy handmaiden of medicine, by the establishment of a chair. Meantime on Sir Archibald Garrod rested the responsibility for any abscess opened in Oxford. During the Napoleonic wars the Medical Society of London had given birth to a child—it might almost be called a war-baby—which had now become a distinguished old lady and was called the Royal Society of Medicine. To the representatives of that and other learned societies he extended a welcome. He hoped that some day the British Medical Association might be able to persuade the public that it was not the General Medical Council. Sir William Leishman, in reply, said that it must not be supposed that doctors in the services did not take the greatest interest in the profession as a whole. They were watching with interest the public encouragement of irregular medical methods, for this might have a practical and awkward application in time of war. If things went on as at present the medical services would be forced to provide osteopathic or Christian scientist healers for the troops, and every officer and man would have to wear an *enlarged identity disc stating* what form of treatment he preferred in given circumstances. These different practitioners would take so much space behind the lines that reinforcements could not be moved into the line. Speaking more seriously, Sir William Leishman said that he hoped that the profession would always be able in an emergency to provide men who could do any ordinary medical or surgical work efficiently. Mr. Townsend, Master of the Clothmakers' Company, also returned thanks to the Society on behalf of the guests.—Dr. E. M. Callender then proposed the President's health. Sir Holburt Waring, he said, was worthy to succeed those who had gone before him—some of whom had been the greatest men in the profession. Sir Holburt Waring, in his reply, said that the Society was prospering greatly. The attendance for the year had been 76 per cent. above the average. This, however, he attributed to the work of the secretaries, Mr. J. E. H. Roberts and Dr. F. G. Chandler. He proposed a toast to them, which was honoured enthusiastically, and they briefly replied.

**Royal College of Physicians of London.**—Sir Thomas Horder will deliver the Lumleian lectures on March 23rd, 25th, and 30th at 5 P.M. at the College. His subject will be Endocarditis, and any member of the medical profession will be admitted on presentation of a card.

**University of Liverpool.**—At a meeting of the Council, held on March 2nd, Emeritus Prof. W. Thelwall Thomas, Ch.M., F.R.C.S., was nominated representative of the University on the General Medical Council, in succession to the late Dr. Richard Caton.

**University College Hospital.**—The annual general meeting was held on March 18th, when an account of the year's activities was given, and the progress of the Rockefeller Foundation gift and the completion of the new maternity home was recorded.

**University of Dublin.**—The Board of Trinity College, Dublin, has appointed Dr. T. Percy C. Kirkpatrick honorary lecturer in the history of medicine in the University of Dublin. Dr. Kirkpatrick holds the degrees of M.D. and Litt.D. of the University of Dublin; he is a Fellow and the registrar of the Royal College of Physicians of Ireland, and a member of the Royal Irish Academy. Dr. Kirkpatrick is the author of several well-known books on the history of Irish medical institutions, including the School of Physic in Ireland, the Rotunda Hospital, and Dr. Steevens' Hospital.

**Hospital Tax in Quebec.**—A Canadian correspondent last week drew attention to various schemes proposed for raising money to reduce the deficit on hospitals. A Bill has now been introduced in the Quebec Legislature to provide that on every meal taken in a restaurant and costing over one dollar (*4s. 2d.*) a tax of 5 per cent. shall be imposed for the support of hospitals.

**Convalescent Home for Derbyshire Miners.**—On the recommendation of the Derbyshire District Welfare Committee a grant of £110,000 has been approved to establish a convalescent home on a site of four acres at Skegness given by the Derbyshire Miners' Association. Provision will be made for 150 patients (including 30 women) and a permanent staff of about 15.

**Association of Special Libraries and Information Bureaux.**—A meeting will be held at the Institution of Mechanical Engineers, Storey's Gate, London, S.W., at 2.30 P.M., on Monday, March 29th, to inaugurate the Association, whose object is to facilitate the coördination and systematic use of sources of information in science, industry, commerce, and public affairs generally. When fully developed it will be a clearing house for those wishing to get into touch with specialised knowledge. Further information may be had from the Organising Secretary, 38, Bloomsbury-square, W.C. 1.

**An American Tour in Europe.**—About 250 American and Canadian members of the Interstate Post-graduate Medical Association of North America, of which Lord Dawson of Penn is president, will arrive in Paris on May 7th to make a post-graduate tour of Italy, Switzerland, Czecho-Slovakia, Austria, Germany, Holland, and Belgium, ending at Brussels on June 26th. The committee invites up to 25 British medical men to join the tour. Further particulars may be had from Mr. Philip Franklin, hon. sec., Foreign Relations Committee of the Association, 27, Wimpole-street, London, W. 1.

## NOTES ON CURRENT TOPICS.

### *Lead Paint Poisoning.*

On Monday, March 15th, Sir William Joynson-Hicks (Home Secretary) presented the Lead Paint (Protection Against Poisoning) Bill, a measure to make better provision for the protection against lead poisoning of persons employed in painting buildings. The Bill was read a first time.

## HOUSE OF LORDS.

### Thursday, March 11th.

### *Coroners Bill.*

On the motion for the second reading of the Coroners (Amendment) Bill,

The **Lord Chancellor** said that the main objects of the Bill were: (1) to carry out the recommendations of a committee which reported in 1910 on coroners; (2) to replace by permanent provisions the provisions of an Act of 1917, the Coroners (Emergency Provisions) Act, which reduced the minimum number of a coroner's jury to seven, and a provision in the Juries Act, 1918, which enabled a coroner to dispense with a jury altogether in a certain limited class of cases; and (3) to deal with a point which was raised in debate last May in the House of Lords—namely, the prevention of unnecessary duplication of proceedings before coroners and justices. This was an amending Bill, and if it was passed, consolidation would become necessary, but it was proposed to reserve that consolidation for a later Bill. Clause 1 of the Bill required that coroners should have a professional qualification, either medical or legal. There was a saving proviso for persons who had served for a period of not less than five years prior to the commencement of the Act as a franchise coroner or a deputy to a county or borough coroner. The provision which prevented an alderman or councillor of a county or borough from acting as a coroner was extended, and there was a provision which abolished the requirement that a county coroner must possess land in fee—a qualification which seemed no longer to be necessary. Clause 3 made provision for the appointment of a coroner for the Isle of Wight. Hitherto, under a special clause, the Governor of that Isle had been appointed coroner and he had appointed a deputy, but with His Majesty's knowledge and approval it was proposed to abolish that old system. By Clause 4 it was proposed to abolish another old system—namely, that of franchise coronerships as from the next vacancy, and incidental to that to enable the Sovereign, if he desired it, to relinquish the right to appoint a franchise coroner in the Duchy of Lancaster. The existence of these franchise coronerships had long been an obstacle in the way of a convenient and economical rearrangement of coroner districts, and he thought that this alteration would lead to economy as well as greater efficiency. By Clause 5 borough coroners, like county coroners, would be paid by salary instead of by fees. Everyone who was cognisant of the system of payment of these county officers would agree that the payment of a salary was better than payment by casual fees, which might vary. It was sometimes said, he thought without foundation, that the fee system induced the coroners to multiply inquests. Clause 6 enabled the council to call upon a coroner to retire upon pension and fixed the maximum amount of pension. There was also a provision to enable the coroner to retire voluntarily, or on medical grounds. Clause 11 provided for the rearrangement of county coroners districts. Under the present law it was done by Order in Council—a somewhat inconvenient and cumbrous method—and it was now proposed to allow the Secretary of State on certain applications to make an order for that purpose. Clause 12 made permanent Section 7 of the Juries Act, 1918. This enabled a coroner to dispense with a jury altogether in certain cases, but it had been suggested that safeguards were necessary before that could be done, and accordingly some additional safeguards were contained in this Bill. The Bill provided that a jury must be summoned if it appear to the coroner (*a*) that the deceased came to his death by murder, manslaughter, or infanticide; or (*b*) that the death occurred in prison or in such a place or in such circumstances as to require an inquest under any Act other than the Coroners Act, 1887; or—and he thought this was new—(*c*) that the death was caused by an accident, poisoning, or disease notice of which is required to be given to a Government Department or to any inspector or other officer of a Government Department, under or in pursuance of any Act; or (*d*) that the death was caused by an accident arising out of the use of a vehicle in street or public highway; or (*e*) that the death occurred in circumstances the continuance or possible recurrence of which is prejudical to the health or safety of the public or any section of the public. He thought their lordships would agree that those were useful safeguards and would secure in those cases in which a public inquest by a jury was especially desirable that a jury should be called. Clause 13 made the viewing of the body obligatory only on the coroner himself. Clause 14 extended the power of the coroner to accept the verdict of a majority of the jury, and also in other cases of disagreement to discharge the jury and begin the inquest afresh, instead of adjourning it to the Assizes as at present. Clauses 15 and 16 were intended to meet the difficulty which had arisen where two deaths arising from the same cause might have occurred in different jurisdictions. In those cases it might be necessary at present to hold two separate inquests by two separate coroners. This clause would enable a body to be taken by order into another jurisdiction, so that only one inquest might be necessary. Clause 17 enabled an inquest to be held by direction of the Secretary of State even when the body was destroyed or otherwise not available. Clause 18 enabled a second inquest to be held where the High Court was satisfied that by reason of the discovery of new facts or evidence it was necessary or desirable in the interests of justice that another inquest should be held. Clause 19 related to cases of suspected murder, manslaughter, or infanticide. Considerable difficulty sometimes arose in those cases from the clashing or simultaneous holding of the coroner's inquest and the inquiry before the magistrates, and he thought that in cases of this kind the inquest should be suspended pending the criminal inquiry. This clause gave effect to that idea. It required that in certain cases of this nature the coroner should, in the absence of reason to the contrary, adjourn the inquest until after the conclusion of the criminal proceedings. He might, if he thought fit, discharge the jury, and then, after the conclusion of the criminal proceedings, he would resume the adjourned inquest if he was of opinion that there was sufficient cause to do so. It was provided that where the inquest was not resumed the coroner must furnish the particulars necessary for the registration of the death. It was added that whether the jury was the old jury or a new one, the issues decided in the criminal proceedings were not to be canvassed at the coroner's inquest. Clauses 20 and 21 provided for certain post-mortem examinations or analyses being made without holding an inquest. The first schedule contained a graduated scale which had been the subject of discussion with those who represented the coroners and which he understood gave satisfaction. He hoped their lordships would give a second reading to the Bill.

After discussion the Bill was read a second time.

## HOUSE OF COMMONS.

### Wednesday, March 10th.

### *Hours of Labour in Shops.*

Mr. **Taylor**, in asking leave to bring in a Bill to amend the Shops Acts, 1912 and 1913, said there was no occupation in the country which employed so large a number of young persons and women as the retail distributive trades, and it was well known from medical statistics that their long hours, and particularly their standing, caused a great deal of bad health among them. The workers in the distributive trades, unfortunately, were not covered by the Washington Convention and therefore it might be that they would be likely to be outside any general legislation. At the present time there was with two exceptions no legal limitation of the hours of labour so far as the mass of shop assistants were concerned. The first of these exceptions was that young persons under the age of 18 were not permitted to be employed for more than 74 hours per week inclusive of meal times, and the second exception was that persons in the refreshment trades were not permitted to be employed for more than 65 hours per week exclusive of meal times. The first clause of this Bill provided for a legal 48-hour week.

Leave to bring in the Bill was granted without a division, and the measure was brought in and read a first time.

### *Deaths from Excessive Drinking.*

Mr. **Scurr** asked the Home Secretary whether he was aware that inquests were held in London during 1925 on 17 persons in which the verdicts attributed the cause of death to excessive drinking, most of the cases being due to the increased habit of drinking methylated spirit; and whether he proposed to introduce legislation to secure that this spirit should be rendered unpalatable for drinking purposes.—Sir **W. Joynson-Hicks** replied: The figure given by the hon. Member is correct and compares favourably with the corresponding figures for 1923 and 1924, which were 31 and 35 respectively. I cannot confirm that the beverage was methylated spirit, but on that assumption the figures give some reason to hope that the introduction of pyridine as an ingredient, which began on May 1st, 1924, has had beneficial results; and the suggestion is supported by a substantial decrease in 1925 of the number of persons convicted of drunkenness whose condition was reported as being due to methylated spirit. The preventive measures already adopted appear to be deserving of further trial before the question of further measures is considered.

### *Sickness and Disablement Benefits.*

Dr. VERNON DAVIES asked the Minister of Health the rate of sickness and disablement benefits granted to a man invalided from either of the fighting services of the Crown for pulmonary tuberculosis under the National Health Insurance Act.—Mr. N. CHAMBERLAIN replied: The normal rates of sickness and disablement benefits for men are 15*s.* and 7*s.* 6*d.* a week respectively. These rates are increased by amounts varying from 1*s.* to 5*s.* a week for sickness benefit, and by half these amounts for disablement benefit, in the case of men who are entitled to additional benefits from their approved societies.

### *Tuberculous Service Men and Pensions.*

Dr. VERNON DAVIES asked the First Lord of the Admiralty if he had formed any opinion as to how the conditions of Service had caused or contributed to the disease of pulmonary tuberculosis for which 11 officers and men were invalided out of the Service in the years 1923, 1924, and 1925, for conditions which had been decided as attributable to the Service; if pensions had been granted these officers and men on account of their disability; and, if not, what compensation had been given them.—Mr. DAVIDSON replied: I regret that on further investigation it is found that in seven cases only was the disease finally decided to be attributable to the Service and not 11 as implied in a previous reply. In five of these cases pensions have been granted by the Admiralty. In the remaining two cases the disease was due to service in the war and the claims were accordingly dealt with by the Ministry of Pensions. The conditions of service causing the disease in these cases were: (*a*) continuity of disease or allied diseases during service and aggravation by service in small craft; (*b*) extraordinary exposure and hardship in submarine service; and (*c*) infection while nursing cases of pulmonary tuberculosis under exceptional exposure.

### *Death Statistics in England and Wales.*

Mr. RHYS DAVIES asked the Minister of Health if he would furnish a return giving the following particulars for England and Wales for each year during the past 30 years—namely, total deaths from all causes; deaths certified by registered medical practitioners; inquest cases; uncertified deaths reported to coroners; and uncertified deaths not reported to coroners.—Mr. N. CHAMBERLAIN replied: The following is the best information available in reply to the question:—

*Deaths Registered in England and Wales.*

| Year | Total. | On medical cert. | On coroner's cert. (inquest cases). | Uncertified. | |
|---|---|---|---|---|---|
| | | | | Reported to coroner. | Not reported to coroner. |
| 1896 | 526,727 | 482,109 | 32,990 | 11,628 | |
| 1897 | 541,487 | 496,515 | 33,869 | 11,103 | |
| 1898 | 552,141 | 507,541 | 34,159 | 7,940 | 2,501 |
| 1899 | 581,799 | 534,446 | 36,608 | 8,435 | 2,310 |
| 1900 | 587,830 | 539,712 | 36,881 | 9,223 | 2,034 |
| 1901 | 551,585 | 504,818 | 36,781 | 8,285 | 1,701 |
| 1902 | 535,538 | 490,091 | 35,793 | 8,251 | 1,403 |
| 1903 | 514,628 | 470,346 | 35,561 | 7,574 | 1,147 |
| 1904 | 549,784 | 505,004 | 35,898 | 7,788 | 1,094 |
| 1905 | 520,031 | 475,018 | 35,667 | 7,145 | 1,001 |
| 1906 | 531,281 | 486,892 | 36,275 | 7,223 | 891 |
| 1907 | 524,221 | 480,151 | 36,474 | 6,759 | 837 |
| 1908 | 520,456 | 476,359 | 36,620 | 6,737 | 740 |
| 1909 | 518,003 | 474,648 | 36,430 | 6,331 | 594 |
| 1910 | 483,247 | 441,480 | 35,109 | 6,041 | 617 |
| 1911 | 527,864* | 483,998 | 37,200 | 6,666 | |
| 1912 | 486,907* | 443,966 | 36,608 | 6,333 | |
| 1913 | 505,026* | 462,417 | 36,419 | 6,190 | |
| 1914 | 516,778* | 472,804 | 37,505 | 6,270 | |
| 1915 | 562,653 | 516,441 | 39,128 | 7,084 | — |
| 1916 | 508,227* | 463,039 | 36,100 | 7,628 | — |
| 1917 | 498,955* | 456,699 | 34,704 | 7,552 | — |
| 1918 | 611,991* | 570,735 | 33,012 | 8,244 | — |
| 1919 | 504,234* | 466,088 | 31,483 | 6,698 | — |
| 1920 | 466,130 | 429,156 | 31,011 | 6,063 | — |
| 1921 | 458,710* | 424,106 | 29,204 | 5,340 | — |
| 1922 | 486,529* | 450,996 | 30,346 | 5,187 | — |
| 1923 | 444,869* | 409,094 | 30,778 | 4,990 | — |
| 1924 | 473,270* | 437,112 | 31,108 | 5,050 | — |
| 1925 | 473,006* | 435,404 | 32,701 | 4,811 | — |

* *Note.*—The required analysis is only obtainable in these years from the provisional Quarterly Returns, and the total shown in the first column may therefore differ slightly from the figure published after correction.

## THURSDAY, MARCH 11TH.

### *Cost of Naval Medical Service.*

On the motion "that Mr. Speaker do leave the chair" on the House going into Committee on the Navy Estimates for 1926–27,

Mr. AMMON said that the medical service seemed to be costing far more than it ought to cost per head in the navy, and he could not see why it could not be coördinated under one head and thus help to simplify the routine work of administration, save a considerable sum of money to the country, give greater efficiency, and knit the Services closer together as a whole than at the present time

Commander BELLAIRS said he thought that the demand of the House for a Ministry of Defence was due to the fact that it was so difficult to bring about coördination through the agency of the House, its Estimates Committee, or its Public Accounts Committee. He had pleaded for single hospitals in naval ports to deal with military and naval needs. It was not until the Geddes Committee was set up that they succeeded in getting the recommendation carried through for single hospitals for the Army, Navy, and the Air Force. But how were they defeated? The Government immediately appointed the head of the Army Medical Service to confer with the head of the Naval Medical Service, and these gentlemen sat down and said, "We will give a sop to the Geddes Committee You naval fellows give up Gibraltar and we of the army will give up Malta"; and then, having given that sop, they shut the lid down on any further reform on the matter Therefore, the House in despair, naturally asked for a Ministry of Defence.

The motion was agreed to by 190 votes to 113.

### *Government and the Factory Bill.*

Major GLYN asked the Home Secretary whether he would consider the desirability of introducing the Factory Bill, with the clauses relating to hours of labour left out, for the purpose of information and consideration, and to indicate the intentions of the Government.—Sir W. JOYNSON-HICKS replied: As I have previously explained, the Government desire, if possible, to arrive first at an international understanding on the general question of hours of labour For that and other reasons the Bill cannot be passed into law this session. I propose, however, to meet what I understand to be the wish of many hon. Members by introducing the Bill for purposes of consultation and discussion later in the session.

### *The Handling of Foodstuffs.*

Colonel DAY asked the Minister of Health if his attention had been drawn to the recommendation contained in the book recently issued by the Royal Sanitary Institute to deal with the handling of foodstuffs; and whether he would see that the suggestions were acted upon.—Mr. N CHAMBERLAIN replied: Yes, Sir; I have received a copy of the book which contains a number of valuable suggestions as to the handling of food. Many of them, as the authors recognise, are more suitable as a basis for propaganda than for statutory regulations, and I hope that they will receive due publicity. The subject of clean food is under the constant attention of my department, and regulations on such questions as meat, milk, and food preservatives have recently been made or published in draft.

### *Medical Services in the Navy.*

Commander BELLAIRS asked the Financial Secretary to the Treasury whether the Committee of Investigation into the rates of pay of the medical services of the Navy and Army and of the new medical service of the Air Force would be allowed to investigate the proposal for a unified medical service for all the fighting forces.—Mr. R. MCNEILL replied: The report of the Weir Committee of 1923 on the amalgamation of services common to the Navy, Army, and Air Force, and the consequential conclusions of the Government as explained to the House on May 30th, 1923, have been made available to the Committee. I am not in a position to anticipate the nature of the Committee's report.

### *Venereal Disease and Vaccination.*

Captain FAIRFAX asked the Minister of Health if the records of his department showed any cases where venereal disease was directly caused by vaccination; and, if so, what number of cases in 1923, 1924, and 1925 respectively.—Mr. N. CHAMBERLAIN replied: There is no record in my department of any such cases since the Vaccination Act of 1898 came into operation, and I am advised that the use of calf lymph, which became general after that Act, renders it impossible for venereal disease to be transmitted by vaccination.

### *Indian Revenue from Opium.*

Mr SCURR asked the Under Secretary of State for India the revenue derived by the Government of India last year from opium.—Earl WINTERTON replied: Figures for the year 1924–25 are not yet available in this country. The gross revenue from opium of the central and provincial governments in 1923–24 was £3,331,000.

### Monday, March 15th.

#### *Indian Subordinate Medical Service.*

Colonel **Applin** asked the Under Secretary of State for India whether he was aware that no promotions to commissioned rank had been made in the Indian subordinate medical service since 1923; and, in view of the number of qualified men who were eligible for and awaiting promotion, would he take steps to ensure that their claims were dealt with at once.—Earl **Winterton** replied: The circumstances were brought to my noble friend's notice by the Anglo-Indian deputation which waited upon him last summer. The Government of India are being asked for an early report on the subject.

#### *Army Medical Service.*

On the motion "that Mr. Speaker do now leave the chair" on the House going into Committee of Supply on the Army Estimates for 1926–27,

Sir L. **Worthington-Evans** (Secretary of State for War) said that last year he had drawn attention to the number of candidates for enlistment who had been rejected as unsuitable on physical and medical grounds. The number was still very high. Out of 89,277 candidates, 52,200 were rejected on physical or medical grounds, or about 58 per cent., which was almost exactly the same proportion as last year. The normal system of promotion in the army up to the rank of major would not be changed, but officers of conspicuous merit would be selected for and granted accelerated promotion. All promotion above the rank of major would be by selection.

The motion "that Mr. Speaker do now leave the chair" was carried by 190 votes to 85.

The House then went into Committee, Captain **Fitzroy** in the chair.

Major-General Sir **Richard Luce** called attention to the present position of the Royal Army Medical Corps. He said it was time that the House realised the deplorable condition to which that corps had been driven, because of the fact that it was unable to obtain the necessary recruits to make up the deficiencies that were taking place. The establishment of the R.A.M.C. in officers, reduced after the war, was now 900; it was something like 1000 just before the war. Now, instead of being 900 as the establishment allowed, it was at present only 794. That was due almost entirely to the fact that they were unable to obtain officers to join the corps. The corps was very well organised when war broke out in 1914, and it did what was expected of it. If there was any breakdown at all in the medical services during the war it was not in the R.A.M.C. but in the Indian Medical Service where public opinion had not been brought to bear and where economy had been over-exerted. The very success of the R.A.M.C. was its undoing. Immediately after the war the economies began and it seemed that the axe not only cut off all the branches, but slipped down and cut the roots as well, until the very sustenance of the whole tree was in danger. Ever since it had been slowly dying from lack of proper nutriment. What were the causes of the present unpopularity of the corps? It was partly due to the fact that the pay, which was fairly satisfactory before the war, had not been increased in proportion to the increase of pay of other branches of the army. A captain's pay in the R.A.M.C. had been increased by only 74 per cent., whereas the pay of a captain in a line regiment had been increased by 88 per cent.; a major's pay had been increased by 49 per cent., as compared with 97 per cent. for a major in a line regiment. The increases of retired pay had been grossly inadequate for certain of the ranks, so much so that at the present time an officer who left the service as a major actually got less than he would have got before the war, in spite of the rise in the cost of living of 75 per cent. above normal. There had been other grievances in the matter of allowances to officers serving in India. The result had been that, whereas it required 45 new recruits every year to make up the wastage in the R.A.M.C., it had only been able for the last three years to get an average of 10, and there was a yearly loss of about 35 officers. In a few years it would be quite impossible to carry on. They were hardly able at the moment to perform those duties which were expected of them, much less the duties which would be expected of them in war. They could only carry on at all at the present time by employing a considerable number of civil medical practitioners in those places where the R.A.M.C. officers should be employed. The result was that a number of officers who had to serve abroad was much larger than it ought to be. This shortage acted in a sort of vicious circle. It made the corps more unpopular because the shorter the numbers the harder it was on those who were left. They had to do far more foreign service, were moved much more, and the senior officers who were left—there were practically no juniors—had to do work which was normally done by junior officers. As the officers of the corps became more and more discontented, it acted in such a way as to prevent fresh officers joining. The difficulties of this corps had been pointed out for at least two years, but up to last October nothing was done to redress the grievances or improve the service. Last October a committee was appointed by the Cabinet to inquire into the services not only of the R.A.M.C. but of the Navy and the Air Force. That committee was still sitting. Various recommendations had been made to it for the improvement of the corps generally; first in the matter of pay, especially those in the middle ranks, majors and lieut.-colonels, who suffered most because their expenses were heavier; secondly, for the removal of the grievances to which he had referred; and, thirdly, the question of granting of a position on the Army Council to the Director-General of the Medical Service. This was considered to be one of the most important considerations. It was of the utmost importance. The medical service had always been at a disadvantage compared with other branches. It was of the utmost importance if that service was to be maintained that it should have a distinct and separate voice in the control of army matters. The committee would soon issue its report, and then the Government would have an opportunity to restore this important branch of the service to popularity and well-being. If they insufficiently appreciated the need a very heavy responsiblity would rest upon them. Should another emergency arise with a R.A.M.C. reduced in strength, insufficiently prepared and organised, who could tell what grave scandal might occur and what would be the declaration of the people when they found such a thing happening? He knew that the Secretary for War appreciated what was happening to the corps, but he appealed to the whole Government and to public opinion.

The vote was agreed to.

### Tuesday, March 16th.

#### Government Economy Bill: Reduced State Insurance Grant.

Mr. **Churchill** (Chancellor of the Exchequer), in moving the second reading of the Economy Bill, said that the first proposal was to reduce the State contribution to Health Insurance from two-ninths to one-seventh for men and one-fifth for women. This would effect a saving of over £2,750,000. The contribution of the State to the Widows and Old Age Pensions Bill was £5,750,000 and the Old Age Pension was granted at 65. This substantially reduced the liabilities for which the Health Insurance fund was responsible by taking off from the beginning of 1925 every contributor between 65 and 70. That was to say, at the very period of life when sickness benefits were at a maximum and would relieve the fund of a responsibility actuarially computed at upwards of £37,000,000. The surplus of the Health Insurance Fund was to-day estimated at no less than £65,000,000. Of this £13,000,000 was due to be spent over the next five years in additional benefits. The Royal Commission had reported that after providing these large additional benefits there would be a surplus of over £2,000,000 per annum after meeting also the cost of medical benefit for which this Bill also made provision. Of course, it would be very agreeable to apply this surplus in still further extending the benefits and it would be easy to unfold many very desirable plans for spending the money. Such plans would, however, automatically attract an additional State grant of £500,000, and, therefore, the increasing prosperity of the insurance fund would from that very fact throw an increasing burden upon the over-strained Exchequer. The Government had, therefore, decided on a general view of the financial situation that the time had come when the State contribution to National Health Insurance could, both in justice and in prudence, be reduced as provided in the Bill.

Mr. **Snowden** moved the rejection of the Bill.

Dr. **Drummond Shiels** said the first essential in the social health insurance system was a complete medical scheme, not only a general practitioner's scheme as the present service was, but a scheme which would give all expert advice, both medical and surgical, and all remedial and curative agencies such as dental and optical treatment, and all kinds of institutional treatment with skilled nursing, and with the help of such accessories as X rays, massage, light treatment, and so one which could not be given in the miserable homes in which so many of the workers lived. The report of the Royal Commission suggested that the various medical services organised by the State should continue to expand both in scope and in the range of the persons to whom they applied. The proposals of the Government in this Economy Bill were made in the face of the findings of an impartial Royal Commission, which recommended the continuance of the Health Insurance service in the present system of contribution partnership, and with its present State grants. If the provisions of this Bill were accepted in respect of the reduction of the State grant it would mean first an alteration of the original terms of the partnership and a dislocation of the finance of the scheme; it also meant thrusting some societies into deficiencies and applied a new guarantee of solvency by the State so far as the payment of treatment and minimum cash benefits were concerned; and it also meant the postponement of the extended system of dental, optical, and other medical benefits. This so-called economy by the Government was a declaration that they did not realise the importance of this great health system to the workers of the country.

### *Miners and Small-pox Infection.*

Colonel DAY asked the Minister of Health for what reason his department refused to sanction the payment of compensation to miners resident in the area of the Wath-upon-Dearne urban district council who were prevented from working owing to the danger of infection from small-pox.—Sir K. WOOD replied: My right hon. friend is advised that it was not necessary, with a view to preventing the spread of infection, for these men to cease their employment. It is understood, however, that the local authority admit their responsibility for the advice given to the men to cease work and desire accordingly to pay reasonable compensation. In these circumstances my right hon. friend is willing to consider further representations from the authority on the question of sanction.

Colonel DAY asked if the hon. gentleman considered that the local medical officer of health was incorrect when he stated that infection might be caught by these men if they went to work.—Sir K. WOOD: No, Sir. I make no such statement.—Mr. W. THORNE asked if there were any reasons why these men should not be given work while there was a small-pox outbreak. They could not prevent them from walking about the streets.—Sir K. WOOD replied that he had already stated that it was not necessary to prevent these men looking for employment.—Mr. T. WILLIAMS asked if Sir K. Wood said that the medical officer of health was entirely wrong.—Sir K. WOOD replied in the negative. He had already stated that he made no comment on the action of the medical officer, one way or the other.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are notified:—Surg.-Comdrs.: J. L. Priston and G. L. Buckeridge to the *President*, addl., for duty in Medical Dept., Admiralty, and as assistants to Medical Director-General; J. G. Boal to the *President*, addl., for three months' post-graduate course; P. L. Gibson to the *Tamar*, addl., for Hong-Kong R.N. Hospital; and C. H. Hawe to the *Tiger*. Surg. Lt.-Comdr. J. G. Sinclair to the *Effingham*. Surg.-Lts. D. C. Drake to the *Mantis* and A. L. McDonnell to the *Montrose*, addl. (on relief), to be accommodated in the *Vampire*.

## ROYAL ARMY MEDICAL CORPS.

Maj. C. Kelly, half-pay list, late R.A.M.C., retires on account of ill-health.

Capt. C. Armstrong is placed on the half-pay list on account of ill-health.

### ARMY DENTAL CORPS.

Temp. Capt. A. A. McMullan, from Gen. List, to be Capt.

### TERRITORIAL ARMY.

Lt. C. A. R. McCay to be Capt.

Lt. S. Orchard (late R.F.A., T.F.) to be Lt.

### TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. F. M. Halley, from Active List, to be Capt.

Sanitary Companies.—Capt. S. Summerson, from Active List, to be Capt.

## ROYAL AIR FORCE.

Flying Officer G. P. O'Connell is granted a permanent commission in this rank.

J. P. Hederman and E. J. Mockler are granted short service commissions as Flying Officers for three years on the Active List.

## INDIAN MEDICAL SERVICES.

Lt.-Col. W. M. Houston, health officer, Port of Bombay, acts as Presidency Surgeon, First District. The services of Dr. W. P. Robson, officiating Chief Inspector of Explosives, have been placed with the Army Department. Maj. H. J. Holgate acts as Superintendent, Special Prison, Aden. Dr. J. F. C. Rose-Meyer, Deputy Superintendent, Mental Hospital, Benares, has been posted to reserve duty at Allahabad. Lt.-Col. Dunn has been nominated a member of the United Provinces Medical Council. Dr. C. H. Mason officiating civil surgeon, has been confirmed Civil Surgeon' The following have been granted leave: *Dr. A. M. Watts*, Medical Officer in Charge, Dufferin Hospital, Lucknow, Maj. H. Scott, Professor of Pathology, King George's Medical College, Lucknow; Dr. O. H. Gade, Civil Medical Charge, Chakrata District, Dehra Dun; Lt.-Col. H. W. Illius, Civil Surgeon, Mussoorie; and Lt.-Col. W. D. Wright, Civil Surgeon, United Provinces.

# Medical Diary.

## SOCIETIES.

ROYAL SOCIETY, Burlington House, Piccadilly, W.

THURSDAY, March 25th.—4.30 P.M. *Papers to be read:* E. B. Verney: The Secretion of Pituitrin in Mammals, as shown by Perfusion of the Isolated Kidney of the Dog. *(Communicated by Prof. T. R. Elliott.) H. W.* Florey and H. M. Carleton: Rouget Cells and their Function. (Communicated by Sir Charles Sherrington.) *Papers to be read in title only:* Seona King: Oogenesis in Oniscus Asellus. (Communicated by Prof. E. S. Goodrich.) R. M. Sargent. The Relation between Oxygen Requirement and Speed in Running. (Communicated by Prof. A. V. Hill.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY March 22nd.—8 P.M., ODONTOLOGY. Blood films and kymographic records of hearts will be shown at 7.30 P.M. Mr. F. N. Doubleday: Action of Local Anaesthetic Solutions on Living Cells.

TUESDAY.—5.30 P.M., MEDICINE. Discussion on Modern Methods of Control of Infectious Disease, opened by Sir John Robertson.

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Dr. J. F. Halls Dally: Ultra-Violet Radiation in Man. Mr. E. Middleton Perry: The Therapeutic Effects of Ultra-Violet Rays and *High-frequency Currents* in Animals (illustrated by lantern slides). Prof. Leonard Hill will open the discussion.

THURSDAY.—8.30 P.M., UROLOGY. Mr. R. H. Jocelyn Swan (President): Some Notes on Cases of Horse-shoe Kidney. Mr. E. D'Arcy McCrea: The Musculature of the Bladder.

FRIDAY.—5 P.M., STUDY OF DISEASE IN CHILDREN. (Cases at 4.30 P.M.) Dr. E. A. Cockayne: (1) Blue Sclerotics *and Brittle Bones; (2) ? Hanot's Cirrhosis. Dr. D. W.* Winnicott: Three Cases illustrating Post-encephalitic Hyperpnoea. Dr. N. Hobhouse: Juvenile Parenchymatous Neuro-syphilis.—8 P.M., EPIDEMIOLOGY AND STATE MEDICINE. Prof. W. J. Wilson: An Account of Typhoid Fever in Northern Ireland. The Library will be open until 10 P.M.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, March 22nd.—8.30 P.M., Prof. Blair Bell, Dr. J. G. Adami, Sir Lenthal Cheatle, and others: The Use of Lead in the Treatment of Malignant Disease.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, March 26th.—8.30 P.M., Dr. G. Riddoch and Dr. P. Panton: Marriage and Syphilis. A discussion will follow.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

*ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.*

TUESDAY, March 23rd.—5 P.M., Sir Thomas Horder: Endocarditis (first Lumleian Lecture).

THURSDAY.—5 P.M. (second Lumleian Lecture).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

MONDAY, March 22nd.—5 P.M., Mr. Shattock: Surgical Affections of the Kidneys.

FRIDAY.—5 P.M., Sir Arthur Keith: Spina Bifida and Allied Conditions.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: FEBRUARY-MARCH, 1926.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, March 22nd.—2 P.M., Out-patient *Clinic: Dr.* Hinds Howell. 3.30 P.M., Mental Deficiency: Dr. Birley.

TUESDAY, Mar. 23rd.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Cerebral Vascular Disease, II.: Dr. Adie.

THURSDAY, Mar. 25th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Physiology of Muscular Contraction: *Dr. Martin.*

FRIDAY, Mar. 26th.—2 P.M., Out-patient Clinic: Dr. Adie. 3.30 P.M., The Cerebro-spinal Fluid in Syphilis: Dr. Greenfield.

The fee for the Course, including Pathology lectures, is £5 5s. For those who hold Perpetual Tickets the fee is £3 3s.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. GREENFIELD, *Dean of Medical School.*

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

*THURSDAY, March 25th.—4 P.M., Dr. A. M. H.* [illegible] Pyogenic Infections of the Skin.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole street, London, W.

Monday, March 22nd, to Saturday, March 27th.—Hospital for Consumption, Brompton, S.W. All-day Course, second week. Operations, lectures, and demonstrations from 10.30 A.M.—Hampstead General Hospital, Haverstock-hill. Second week of Course for Practitioners in all departments of the Hospital throughout the demonstrations.—London School of Hygiene and Tropical Medicine, Endsleigh-gardens, N.W. Tuesday and Thursday, 2 P.M., Dr. Low and Dr. Manson-Bahr: Special lecture-demonstration illustrated by cases in hospital.—Chelsea Hospital for Women, *Arthur street*, S.W. Post graduate Course in Gynæcology. Daily operations, lectures, demonstrations, &c. (Third week.) Further information from the Secretary of the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Monday, March 22nd.—10 A.M., Surgical Out-patients: Mr. W. E. Tanner. 10.30 A.M., Gynæcological Operations: Mr. A. E. Giles: Throat, Nose, and Ear Operations: Mr. W. Ibbotson. 2 P.M., Medical, Surgical, and Gynæcological Clinics, Operations. *6.30 P.M., Venereal Department.*

Tuesday.—2 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics, Operations. 4.30 P.M., Dr. A. J. Whiting: Value of the Reflexes in Diagnosis.

Wednesday.—10.30 A.M., Surgical Operations: Mr. E. Gillespie. 2 P.M., Medical, Eye, and Skin Clinics, Operations. 5.30 P.M., Venereal Department.

Thursday.—10.30 A.M., Dental Out-patients: Mr. E. S. Pierrepont. 2 P.M., Medical, Surgical, and Throat, Nose and Ear Clinics, Operations. 5 P.M., Operations.

Friday.—10.30 A.M., Eye Operations: Mr. N. Fleming. 2 P.M., Surgical, Medical, and Children Clinics, Operations. 3 P.M., Gynæcological Clinic. 6.30 P.M., Venereal Department.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

Tuesday, March 23rd.—4.15 P.M., Mr. C. Roberts: Atypical Forms of Acute Appendicitis.

Friday.—4.15 P.M., Dr. J. Wharton: Demonstration of Ophthalmic Cases.

## Appointments.

Douglas, Charlotte A., M.D. Glasg., has been appointed Medical Officer to the Scottish Board of Health.

Mann, Ida C., M.B., B.S. Lond., F.R.C.S. Eng., D.O.M.S., Assistant Surgeon to the Central London Ophthalmic Hospital.

Yates, H. B., M.B., B.Ch. Camb., F.R.C.S. Eng., Part-time Demonstrator in Anatomy in the University of Sheffield.

St. Thomas's Hospital: Maxwell, L. B., M.B., B.Ch. Camb., Medical Secretary to the School; Cole, L. B., M.B., B.Ch Camb., M.R.C.P. Lond., Resident Assistant Physician; and Cooke, A. M., M.B., B.Ch. Oxf., Medical Registrar.

Certifying Surgeons under the Factory and Workshop Acts: Davies, I. H., M.B., Ch.B. Liverp. (Cerrig-y-Druidion District of the County of *Denbigh*); *Parry*, G. W. V., L.R.C.P. Lond., M.R.C.S. Eng. (St. David's District of the County of Pembroke).

## Vacancies.

*For further information refer to the advertisement columns.*

*Accrington, Victoria Hospital.*—H.S. £150.

*Belgrave Hospital for Children, Clapham-road, S.W.*—H.P., H.S., and Asst. H.P. Each at rate of £100.

*Birmingham City Mental Hospitals.*—Asst. M.O. £350.

*Bristol Mental Hospital.*—Sen. Asst. M.O. £550.

*Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.*—Sen. and Jun. H.S. At rate of £100 and £50 respectively.

*Central London Throat, Nose, and Ear Hosp., Gray's Inn-road, W.C.*—Hon. Asst. Out-Patient Reg.

*Durham County Council.*—Dist. Tub. M.O. £600.

*Evelina Hospital for Children, Southwark, S.E.*—H.S. At rate of £120. Also Hon. Asst. Aural S.

*Hampstead Borough.*—Four Consulting Obstetricians.

*Hospital for Diseases of the Throat, Golden-square, W.*—Med. Reg.

*Hospital for Sick Children, Great Ormond-street, W.C.*—H.S., H.P., and Asst. Cas. O. £50 in each case.

*Hospital of St. John and St. Elizabeth, 40, Grove End-road, N.W.* Res. H.P. and H.S. At rate of £100 and £75 respectively.

*Hull and Sculcoates Dispensary*—M.O. £500.

*Leamington Spa, Warneford General Hospital.*—Res. H S. £150.

*Liverpool, Walton Institution, Rice lane.*—Res. Asst. M.O. £200.

*London Lock Hospital, 283, Harrow-road, W.*—Second H.S. £150.

*Manchester, Ancoats Hospital.*—H.S. At rate of £100. Also Asst. M.O. in Ven. Clinic. £1 1s. per clinic.

*Manchester Babies' Hospital, Burnage-lane, Levenshulme.*—Res. M.O. At rate of £125. Also Non-Res. Clin. Asst. At rate of £50.

*Manchester Children's Hospital and Northern Hospital for Women and Children.*—Pathologist. £400.

*Manchester Committee on Cancer.—Pathologist. £1000.*

*Manchester Royal Infirmary, Roby-street.*—Res. M.O. Also Asst. M.O. At rate of £200 and £100 respectively.

*Metropolitan Asylums Board.*—Asst. Pathologist. £700.

*Mount Vernon Hospital, Northwood, Middlesex.*—Hon. Asst. Actino-Therapeutist.

*National Hospital for the Paralysed and Epileptic, Queen-square, W.C.*—Orthopædic S.

*Newcastle-upon-Tyne Hospital for Sick Children.*—Sen. and Jun. Res. M.O.'s. At rate of £120 and £100 respectively.

*Northumberland County Council, Wooley Sanatorium, near Hexham.*—Asst. Med. Supt., &c. £600.

*Norwich, Norfolk and Norwich Hospital.*—H.S. £120.

*Oxford, Radcliffe Infirmary and County Hospital.*—Hon. S., Hon. Asst. P., and Hon. Asst. S.

*Paddington Green Children's Hospital, W.*—H.P. and H.S. Each £150.

*Prince of Wales's General Hospital, Tottenham, N.*—Two H.S.'s and one H.P. At rate of £120. Also Jun. H.S. and Jun. H.P. At rate of £90.

*Redhill, Surrey, Royal Earlswood Institution.*—Jun. Asst. M.O. £250.

*Rochdale Infirmary and Dispensary.*—Jun. H.S. £200.

*Royal Dental Hospital of London, 32, Leicester-square, W.C.*—House Anæsthetist. 10s. 6d. per attendance.

*Royal National Orthopædic Hospital, 234, Great Portland-street, W.*—H.S. At rate of £150.

*Royal Westminster Ophthalmic Hospital, King William-street, Strand, W.C.*—Asst. S.

*St. Andrew's Hospital, Devons-road, Bow, E.*—Med. Supt. £1000.

*St. Leonards-on-Sea, Buchanan Hospital.*—H.S. £150.

*Sheffield Royal Infirmary.*—Jun. Aural and Ophthalmic H.S. £80.

*Southampton County Borough.*—Tuberculosis O. £750.

*South London Hospital for Women, South Side, Clapham Common, S.W.*—H.P. and three H.S.'s. All at rate of £50.

*Stockport Infirmary.*—Hon. P. and Hon. S.'s.

*Sunderland Borough Mental Hospital, Ryhope.*—Asst. Med. Supt. £500.

*University of London, King's College for Women.*—Head of Dept. of Hygiene and Bacteriology, &c. £400.

*West London Hospital, Hammersmith-road, W.*—Hon. Med. Radiologist.

*Willesden Urban District Council.*—Consulting Ophth. S. 4 guineas per session.

*Wrexham and East Denbighshire War Memorial Hospital.*—Hon. Asst. P.'s., Ophth. S., Pathologist, and Dental S.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacancy for a Certifying Factory Surgeon at Kilmarnock (Ayrshire).

## Births, Marriages, and Deaths.

### BIRTHS.

Chance.—On March 11th, at Clarges-street, W., the wife of Dr. R. Maxwell Chance, of a daughter.

Corkey.—On March 13th, at Epsom, the wife of I. W. Corkey, M.C., F.R.C.S., of a son.

### DEATHS.

Dickson.—On March 12th, at Llanbedr Hall Sanatorium N. Wales, David McMurray Dickson, M.C., M.R.C.S., L.R.C.P., aged 34.

Milton.—On Feb. 23rd, suddenly, in Cairo, on his way to India, Francis Ralph Septimus Milton, F.R.C.S., M.R.C.P.

Permewan.—On March 9th, William Permewan, M.D., F.R.C.S., J.P., of Normanton-avenue, Liverpool, aged 61 years.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Royal Medical Benevolent Fund.—At the last meeting of the Committee 48 cases were considered and £620 voted to 12 applicants. The following were some of the cases relieved:—

M.B., 1882, married, has been an invalid for 25 years and has the constant attention of his wife. Their total income amounts to £156 per annum, and the house they live in is their own. Rates average 14 guineas per annum. One daughter, aged 34, is married with three children and lives in Rhodesia. Voted £30 in 12 monthly instalments.

Daughter, aged 58, of L.R.C.P. & S. who died in 1878. Has been a nursery governess and mother's help, but is now only able to do very light work. She is at the end of her resources. Friends gave her some help. Board residence amounts to 28s. a week. Voted £18 in 12 monthly instalments.

Widow, aged 69, of M.B. who died last year. Husband had been in receipt of a grant four months prior to his death. Applicant is at present living with married daughter who is unable to give any monetary help. Total income £20 from investments. Friends gave £26. Board-residence amounts to 25s. a week. Voted £26 in 12 monthly instalments.

Daughter, aged 71, of M.D. who died in 1859. Applicant asks for assistance as her sister, who was a grantee of the Fund, died at Christmas. Applicant received from friends £52 and she made £14 by plain sewing. The rent of her cottage is 4s. 6d. a week, and rates £5 per annum. Voted £5.

Widow, aged 68, of L.R.C.P. & S. who practised in the north of England and died last month after some years of illness. Husband had been in receipt of an annuity from the Fund of £10 per annum and also had the Old Age Pension. An adopted daughter lives at home and contributes £1 a week out of her earnings of 30s. a week. Applicant has no income whatever apart from the daughter's money. Voted £26 in 12 monthly instalments.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, K.B.E., at 11, Chandos-street, Cavendish-square, London, W. 1.

## PUBLIC HEALTH IN PERSIA.

## 1914–24.

BY A. R. NELIGAN, M.D. LOND., M.R.C.S., D.T.M. & H. CAMB.,

PHYSICIAN TO H.M. LEGATION, TEHRAN; BRITISH REPRESENTATIVE ON THE PERSIAN SANITARY COUNCIL.

No connected account of public health questions in Persia has been published since the year 1910, except for a report by the writer on the influenza epidemic of 1918.[1] Reasons are not wanting for collecting in a single paper information which, though available, is scattered through numerous reports and minutes. The following are some of them.

1. The difficulty of obtaining (for reasons which will appear) correct information on the epidemiology of Persia and on sanitary matters in general in the country; this applies to residents and must do so with greater force to authorities abroad. Thus, in the *Times* of May 5th, 1924, in an article on the "Ravages of Malaria," the Persian Sanitary Council was represented as having reported to the League of Nations that "recurring epidemics of cholera, plague, relapsing fever, small pox, typhoid, typhus, and malaria, lasting sometimes several years have occurred throughout Persia during the last 11 years." This alarming account was exaggerated, to say the least of it, and the Sanitary Council must be excused direct responsibility for it. It was, however, to be read in the light of an appeal to the League from Tehran for help in combating malaria.

2. The importance of studying from time to time Persia's position in the international sanitary situation. Foyers of plague have been described; are there any to-day? Are any of the other great epidemic diseases endemic? Is Persia a channel for the transmission of disease from east to west?

3. Changed communications with Persia. After the Bolshevik revolution the usual route between Europe and North and Central Persia was closed and replaced by the long journey via Bombay, the Persian Gulf, and Mesopotamia. Now this latter route is falling into disuse and the new trans-desert route from Beyrout to Bagdad has again brought Persia within 10 or 13 days of London. Incidentally, this same route, continued via Iraq and the Persian Gulf, has brought India within nine days of the eastern Mediterranean.

1. The extension of railways to two fresh points on ersia's frontiers. In the south-east the line from Quetta Nushki has been prolonged to Duzdab on the Persian de. In the west the military railway made by the British rmy from Basra to Bagdad was continued to Quraitu on he frontier. Later, in 1921, the terminus was withdrawn o Khanikin, 18 miles from the Persian frontier.

5. The introduction of motor transport and therefore of nore rapid internal communications.

6. The opportuneness of describing any progress made n sanitation, medical education, and the practice of medicine n Persia.

7. The fact that during the war and after it parts of Persia were fought over and occupied by British forces.

Lastly, the "opium question." Recent international discussions have brought out its importance, and no account of public health matters in Persia can omit it.

### *Geography and Climate.*

Reference has been made to the difficulties experienced in obtaining accurate sanitary information about Persia. It will be well to start by describing some of them, all the more so that if they are realised much that comes later will be more easily understood. They are physical and administrative.

Persia covers a bigger area than do France, Belgium, Germany, and Spain together, but her population is only 10 million at the most, of whom 2 million are nomads whose yearly migrations cover immense tracts. Except for the littorals of the Caspian Sea and the Persian Gulf, the country is an elevated plateau 2000 to 5000 ft. above the sea. The central and eastern portion is a vast, waterless desert. The rest is cut up by high mountain ranges into deep valleys and wide plains. These ranges encircle the desert in their general tendency to run from north-west to south-east. They cut off one district from another and make communication difficult. Main roads are few and bad; journeys are slow even by motor-car. The difficulties of travel are increased by heat in summer, by snow in winter, and by floods in spring. There are no railways, though the towns of Tabriz and Duzdab are connected with external systems. There are many hundreds of miles of mountain or desert frontier and of lonely sea-coast. Telegraphic and postal communications are possible only with the larger towns and along the main routes.

A word about climate to conclude this short sketch of the physical features of Persia. That of the plateau is dry and exhilarating; the sun is seldom clouded; the rainfall is low (8 to 12 in.) and is limited to the period October to May. The hot summer is followed by a cold winter, and the thermometer, which may reach 120° F. in the less elevated parts in July or August, may fall to well below zero in higher districts in December or January. The Caspian provinces, on the other hand, are damp and depressing with their cloudy skies, high rainfall (50 to 60 in.), and moderate temperatures. The shores of the Gulf combine high humidity with great heat; again the rainfall is low—8 to 10 in.

### *Medical Education.*

The efficiency of the health services of a country depends on a regular supply of properly trained medical officers. Medical education in Persia, in spite of years of experience and expense, is, it must be candidly stated, of a very low standard. A State diploma has been in existence for some 40 years. The medical school is at Tehran; it is very poorly equipped and the teaching is largely theoretical. No fees are charged. There is a long list of so-called professors, two (the lecturers on surgery and bacteriology) are French, the others are Persians, some of whom have French diplomas. The two Europeans have no say in the management of the school. Dissection is not permitted by the religious law. Hospital attendance is not compulsory. The young diplômés prefer to remain in Tehran or in one of the larger towns. There is a great need of well-trained doctors, especially in the country districts, and there is no source of supply of men adequately equipped, in the modern sense of the word, for quarantine work, for special posts during epidemics, for the newly-organised and enlarged army, or as municipal and provincial health officers. The difficulties of the public health authorities at Tehran in dealing with emergencies or in obtaining accurate information may well be imagined. Indifferent medical training lies at the source of most of these difficulties, and though some improvements have been noted of late, it is not easy to see how any great advance can be made, unless more students are sent abroad, or unless the medical school is reorganised under Western supervision.

### *Central Sanitary Administration.*

The Persian Sanitary Council has, except for one short interval in 1921, continued to be the chief sanitary authority. This body, though a Persian department, has foreign representatives sitting on it, and in this respect resembles the defunct Constantinople Board of Health. The President, up till the outbreak of the war, had always been one of the French doctors in Persian employ. The Persian members are 12 *membres titulaires*, all doctors, together with representatives of ministries (Foreign Affairs, Interior), the police and customs departments. Besides these there are an unlimited number of *membres honoraires* without votes. In 1911 the British, American, French, Russian, and German Governments were represented by the medical officers of their legations. The Austro-Hungarian Government sent a special delegate and the Constantinople Board was also represented. Other European members were the medical superintendent of the Indo-European Telegraph Department (Government of India), the two French professors in the medical school, and a veterinary surgeon. The British, American, French, and German Legations are still represented. There are local sanitary commissions at Tabriz and Meshed.

Up till the year 1921 the council was a dependency of the Ministry of the Interior. After the coup d'état of that year a ministry of health was formed and the council became a purely advisory body for a few months. Then the ministry was closed and the council placed under the Ministry of Public Instruction.

As regards the duties of the council, they are primarily to deal with epidemics and to make quarantine arrangements on the frontiers. As the sole sanitary authority in the country, however, it has found itself constrained to take the lead in all sorts of parochial questions—public vaccination, for instance—and is consulted on every imaginable subject having any connexion at all with medicine. It has a small annual budget for the expenses of its secretariat, and up to the outbreak of the late war it received an annual sum of roughly £5000 for dealing with epidemics. This payment ceased and requisition had to be made for funds as necessity arose. Persia has for years been in a state of great financial stringency, and, naturally, the sanitary services have not come off best in the struggle to gain the ear of the Treasury. Still, it must be admitted that the Government has done its best in difficult circumstances to give effect to the recommendations made to it. Another source of revenue specially earmarked for the vaccination service and the purchase of sera and vaccines—namely, a tenth of the tax on vehicles and animals—has lapsed, at any rate, in its original form, and of late years only just enough has been received to keep the service alive. With the introduction of new financial arrangements by the American advisors in 1923, a budget for the sanitary services had to be presented, and the first, that for 1924–25, amounted to £27,000 at par. This did not include the municipal services.

---

[1] Reports on Public Health and Medical Subjects. No. 4. Report on the Pandemic of Influenza, 1918–19. Ministry of Health.

The council holds monthly meetings throughout the year. Business is discussed in either Persian or French, and the minutes are printed in French. There are three permanent commissions—hygiene, finance, and personnel. The *Commission d'Hygiène* holds frequent meetings and during epidemics has executive powers.

The duties of the Sanitary Council may be summed up as follows: (1) To act as advisory body to the Persian Government on all questions of public health and international sanitation. (2) To deal with epidemics in the country. (3) To organise and supervise the sanitary defences of the frontiers. (4) To receive and collate sanitary reports. (5) To carry on public vaccination. (6) To supervise the importation and distribution of morphine, cocaine, and their derivatives.

Since the above paragraphs were written yet another change has been made in the sanitary administration. By order of the Sardar Sepah, Prime Minister and Minister for War,[*] by far the most forceful character in Persian politics for many a long day, it has been attached to his department. The President of the Sanitary Council has been made Director of Public Health Services. The council remains as principal advisory body. The financial situation of the country is improving, but the standard of medical education must be raised for progress to be made in public health matters.

### *Municipal Health Services.*

In 1919 the Sanitary Council put forward a scheme for a health service for the large towns, but little progress has been made except in the capital itself.

In Tehran (population estimated at 230,000) there had been a nominal principal medical officer of health for some years, and in 1917 five assistants were given to him, one for each quarter of the city. In 1916 a public asylum was opened by the police administration and was later transferred to the municipality and enlarged. In 1921 the Tehran municipality was completely reorganised as an independent administration, and a medical service formed. A number of treatment centres for the poor were opened: six general, one for women, one for venereal diseases, and two dental. A municipal hospital of nominally 100 beds was also created. In 1918 a poorhouse and an orphanage were opened. The former now accommodates some 100 persons and the latter some 700 children. In 1923 a creche for foundling infants was opened.

*Water Supplies.*—In 1923 the municipality assumed responsibility for the distribution of water. The supply of some towns, such as Isfahan and Resht, is by wells, but in most places, including the capital, the water is derived from distant underground springs. These are brought to where the water is required in artificial channels (*qanaats*), still underground, which gradually approach the surface. Thence the water runs in open courses. It is drunk as well as used for irrigation and all domestic purposes, including the special ablutions of Mussulmans. For the Mussulman running water is pure. There are three public laundries in Tehran, but it has been found impossible to check the washing of clothes in the water channels. As regards Tehran, with a magnificent catchment area close at hand (the Elburz chain), it would be easy to provide a piped water-supply.

*Certification of Death.*—The Tehran Municipality introduced death certificates in 1922; they are collected by the washers of the dead. Their value as a basis for mortality statistics is limited, however, by the fact that a symptom such as ascites is often given as the diagnosis, and that not all bodies, though nearly all, are taken to the public washers. Further, while the washers have orders to refuse to deal with bodies which are not accompanied by a certificate, neither a statement as to the cause of death nor the signature of the medical attendant is necessary, and the certificate is often signed by a medical officer of health. It will be seen from the list given below that in the case of more than one-sixth of the total deaths in Tehran in a single year the cause has been returned as unknown. This is partly to be explained by the fact that it is common for doctors to be changed several times during an illness, and that the poor do not, as a rule, seek medical advice when it is clear that there is no hope of recovery. A medical officer confronted with such cases is naturally often unable to state the cause of death (the religious law forbids autopsies), but he always gives a certificate provided that he is satisfied that there is no question of crime. The certificate is therefore in a large number of cases simply a permit to carry out the last rites. Since, however, the mortality lists issued by the municipality are the only statistics of the kind obtainable in Persia, those for one year are given below as sufficient to show the principal causes of death in the largest city. The list may be taken as an average specimen; it is very like those for the two previous years.

| Total .. .. | | 4522 |

*Notes.*—The 608 cases of "pleurisy" certainly include many cases of pneumonia, whilst much bronchitis has evidently been classed as pneumonia. The deaths from whooping-cough are presumably from broncho-pneumonia and the 49 from measles might equally well be placed under disease of the respiratory system, thus still further adding to the mortality due to this cause. The low figure for heart disease (44) is explained partly by the fact that acute rheumatism is rare. "Paralysis" certainly includes a number of cases of syphilitic myelitis, and ascites includes many cases of malarial cachexia.

Taking the population of Tehran as 230,000, the total of 4522 deaths for the year in question works out at a mortality of 19·66 per 1000. One-quarter of the total number of deaths occurred in infants under one year of age. In the three years for which statistics have been published two deaths were attributed to appendicitis, three to diabetes, three to rabies, one to alcoholism.

*Hygiene.*—There is one schools medical officer for Tehran. He is employed by the Ministry of Education. The schools, as indeed all the institutions mentioned above, are in ordinary houses more or less adapted to the purpose in view, and not in special buildings. The municipality has drawn up regulations for restaurants, public baths, establishments where the dead are washed, abattoirs and butchers' shops, and chemists. All the innovations described are steps in the right direction and worthy of all praise. Their value is, however, diminished by the lack of training of the medical personnel. Urban conservancy—progress has been made in street cleaning and lighting at Tehran, and a water-cart has appeared—public latrines and private closets, malaria prophylaxis, drinking-water supplies, protection of perishable food, and slaughter-houses are some of the more important untouched problems. In the largest towns the public baths which play such an important part in the life of the people are being improved, and the common hot-water tank is giving way slowly to the douche system.

A simple pit of greater or less depth is still the sole sanitary contrivance in Persia; the absorbent nature of the soil in the greater part of the country is well suited to it. Uncared for, as it frequently is, it becomes an intolerable nuisance and danger. In the towns there is a great scarcity of public latrines, and most waste pieces of ground are used as squatting places.

*Provincial Services.*—During recent years a number of sanitary medical officers were appointed for the provinces.

---

[*] [illegible] King of Persia on Oct. 31st, 1925.—Ed. L.

Like most Persian health officers, they had had a moderate clinical training but no special teaching in sanitation, bacteriology, &c. They had no laboratories to which to refer and no disinfecting apparatus, or, indeed, supplies of drugs. Owing to non-payment of their salaries some have left their posts.

### *Frontiers.*

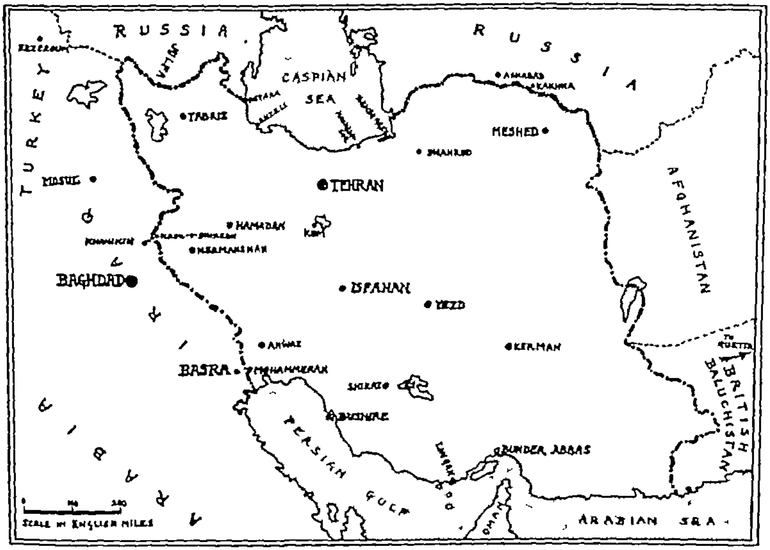
As will be evident from the section on epidemics, the countries bordering on Persia either have endemic centres of plague and cholera, or are liable to outbreaks of those diseases. The watching of many thousands of miles of frontier is as difficult for her sanitary administration when the need arises, as it is for her customs officials. Fortunately the need is not as continuous; and also, fortunately, the frontiers are usually crossed or crossable at fairly definite points only, while elsewhere arid plains or pathless mountains offer an effective barrier to the introduction of epidemics, as well as to their spread in the interior. Persia is a signatory power of the later international sanitary conventions.

*Persian Gulf Quarantine Service.*—This service as being the best equipped is mentioned first. There are at present, and have been for the last 16 years, five quarantine stations equipped with disinfecting apparatus along the Persian Gulf littoral. The Government of India has continued to lend medical officers to the Persian Government for this service. The chief quarantine medical officer with two assistants resides at Bushire, and the subordinate personnel is Persian.

There is accommodation at each station for first-, second-, and third-class passengers, and disinfecting apparatus. Of recent years the Persian Government has spent little on the buildings, and there is need of landing jetties for small boats. As is well known the Persian ports have no harbours and ships have to lie off the shore at a distance varying from three to nine miles. This entails no small hardship on the medical officers.

A study of the sections on plague and cholera will show that the service provides an important obstacle to the introduction of these diseases from India and the opposite coast of the Gulf. To deal with the regular large shipping is a comparatively simple matter, and its greatest difficulty lies in coping with the *cabotage* along so many miles of lonely coast-line. The inhabitants on the other side of the Gulf have an unpleasant habit of fleeing in small craft to the Persian side whenever plague appears among them. It would seem, however, impossible to design anything better than the present line of stations with customs officials and other coast watchers in between. That the small boat menace can be, and is being, effectively dealt with was shown, for instance, in the case of Lingah in December, 1923. There the medical officer found cases of plague landed down the coast, probably from Dobai on the opposite shore of the Gulf, and dealt with them and contacts, so that there was no spread of the disease.

*Russo-Persian Frontier.*—The trans-Caucasian frontier has been defended at important points such as Julfa, where the railway line from Tiflis to Tabriz enters Persia, Shahtakht, and Khudafarin, by means of sanitary posts improvised as the need arose. There are no permanent medical officers, buildings, or disinfecting apparatus. Similar conditions exist in the trans-Caspian frontier, where the railway from Krasnovodsk approaches Persian territory. The points usually chosen for quarantine stations are opposite Ashkabad, Kaakha, and Sarakhs. On the Caspian adequate quarantine stations were built in 1912 at the ports of Enzeli and Astara and supplied with disinfecting stoves. That at Astara has been practically destroyed by storms and the encroachment of the sea. At Enzeli, the most important Persian port on the Caspian, the station is in little better state as a result of the passage of Russian troops during the war and subsequent local disturbances. Medical officers are posted at each place. The ports of Mashadi-Sar and Bendergez have no quarantine stations; the doctors of the local customs offices carry out port duties in case of need.



*Eastern Frontier.*—The most important trade route crossing the Eastern frontier is the railway line from Quetta to Duzdab in the Sarhad. This line was continued from Nushki to Duzdab during the war and a small town has sprung up at the latter place. So far the Persian Government has not found it necessary to take any special sanitary measures on this route. The Sarhad is separated from India by the whole of British Baluchistan, and neither plague nor cholera has appeared in that province.

*Western Frontier.*—The Turco-Persian frontier is crossed by numerous routes, the most important being that which runs to Erzerum and Trebizond. There are no quarantine establishments. The Perso-Iraqi frontier is crossed by the extremely important Kermanshah Bagdad road at Kasr-i-Shirin. This has always been the most important pilgrim route in Persia, for it leads through Bagdad to the Holy Shiah cities of Najef and Kerbela, to which places, moreover, many corpses are taken for burial. Its importance has been trebled however of recent years, for during the war the British Army in Mesopotamia built a railway to Quaraitu on the Persian frontier six miles north of Kasr i Sh

further, after the Russian revolution in 1917, it

principal route into northern and central Persi

1923, too, when the trans-desert route from the Me to Bagdad was opened, the journey from Persia to the West was still further shortened and the route is likely to be always a popular one among through travellers. The railway terminus has now been moved back to Khanikin, 18 miles inside the Iraq frontier, whence there is a regular motor service into Persia.

From the sanitary point of view, however, the importance of the route will always be its use by pilgrims, and this will be discussed under another heading. There are no permanent sanitary officers or buildings on the frontier. In times of need doctors have been sent to Kasr-i-Shirin, and a quarantine station improvised out of tents and old customs godowns in very bad conditions.

To the south of Kasr-i-Shirin there is a customs post at Soumara opposite Mandali, and this was used as a quarantine post in 1923. Further south still the Anglo-Persian Oil Company have, at their refinery on the island of Abadan, a fully-equipped port sanitary service (see "Epidemics: Plague"). During epidemics the same company has inspection posts at Sayed Hassan on the Karun River and at Dar-i-Khazineh, for traffic going by river or road to the oil-fields. At Kut Abdullah below Ahwaz there is an isolation hospital and inspection post for boats.

### *Pilgrim Traffic.*

The most famous Shiah Shrines, as has been stated, are in Iraq. The number of passports issued to pilgrims in the last normal year (1921–22) was 11,609, of which over 11,300 were delivered in Kermanshah. These figures do not, however, represent the total number of pilgrims, for several members of a family may be on one passport. More than half pass between September and November. The greatest number passing in a day has been 1000.

The number of dried corpses passed through Kasr-i-Shirin for burial at Kerbela in the year 1922–23 was 4200. There is an inspection service in charge of a Persian doctor at Kermanshah. A fee is charged, but the receipts of late years have not exceeded the expenses of collection.

Plague is endemic from Bagdad to Basra and the pneumonic form has been reported. Cholera also appears from time to time. The question of adequate sanitary supervision of the pilgrim traffic along the Kermanshah-Bagdad route has therefore always been a source of anxiety to the Persian authorities. This has not been diminished by the recent provision of more rapid transport by rail and road between the interior of Iraq and Persia. While making the pilgrimage more easy, it has brought at the same time possible centres of infection nearer to the frontier than in the days when the journey had to be done with transport animals or horse-drawn conveyances. On the other hand, the organisation of a health service by the British authorities in Iraq has led to early notification and prompt action whenever either plague or cholera appears, so that the chances of unobserved spread are considerably diminished. Indeed, in the year 1923, when there was a sharp epidemic of cholera in Iraq, there is little doubt that the energetic action of the health service was the principal factor in preventing the spread of the disease to Persia. The methods employed included an extensive inoculation campaign and a system of permits to travel, with numerous observation posts.

### *Quarantine Stations.*

Returning now to the pilgrim route itself, it is to be noted that at Khanikin on the Iraq side of the frontier, the terminus of the line from Bagdad, the Turkish authorities had for many years a quarantine station, and that on more than one occasion, at the request of the Persian Government, they undertook the inspection and disinfection of travellers returning to Persia during an epidemic in Mesopotamia. The Iraq authorities have recently built a new and up-to-date quarantine station at the same town, and in 1923, at the request of the Persian Government, agreed to inspect travellers en route for Persia during the epidemic of cholera.

On the Persian side of the frontier there is, as has been mentioned, no permanent quarantine station. The Sanitary Council has at repeated intervals during the last ten years, and indeed during the previous ten also, proposed the construction of one. The site favoured is near Kasr-i-Shirin, a village on the frontier; but the Pass of Paitaq, some 40 miles within the frontier, has its advocates. The construction of an up-to-date establishment has, however, been beyond the means of the Government, and the matter is no nearer a solution than it was. Perhaps there has been at the same time, on the part of those who have held the purse-strings, a certain hesitation to launch out into any large scheme until a greater certainty of including in it a well-trained staff exists.

There is another possible solution of the difficulty which would appear to be both practical and economical. On a straight road running between two points and presenting no particular natural features, why is it necessary to have two quarantine establishments at a distance of 18 miles from each other? Could not the temporary arrangements already described, made on occasion between the Persian authorities and those at Khanikin, become permanent and the station at that place be made to deal with the traffic in both directions? As a matter of fact this and other sanitary questions involved by a common frontier have been the subject of proposals by the Iraq sanitary authorities, which have been favourably received by their Persian opposite numbers. As soon as regular relations have been established between Persia and Iraq, the two Governments will do well to draw up a common scheme of sanitary defence in which their respective health services can take part, to the great benefit of both countries. The basin of the Shatt Arab and the Kermanshah-Bagdad road will absorb their attention at the start.

In the event of an epidemic in Iraq the Persian Government has been in the habit of stopping the pilgrim traffic. At the same time the Government of Iraq has, should the epidemic be cholera, refused to allow travellers from Persia to proceed beyond Khanikin unless provided with certificates of recent inoculation. For the present precautions of this nature appear to be the best that can be devised for the well-being of the two countries.

### *The Shrines.*

The shrines of the Imam Rezah at Meshed and of Fatimah the Immaculate at Kum attract many pilgrims. They are also favourite places of burial. Kum is more particularly a local, that is to say a Persian, place of pilgrimage. Many better-class people visit it every year. In 1919 the attention of the Sanitary Council was drawn to the dirty state of the town. In the following year the council urged that burial should not be allowed inside the town, but so far it has been found impossible to prevent the practice entirely. There is no hospital. Kum may be reached by motor-car on all the main routes converging on the town.

Meshed is visited annually by many thousands of Persians as well as by a number of Indian Shiahs, generally on their way home from Kerbela and Najef. Persian authorities give the normal permanent population as about 40,000 souls, and say that there is a floating population of pilgrims more or less in residence of about the same number. There is a local sanitary commission under the Sanitary Council. Meshed has for part of the city a piped water-supply, and is alone in this respect among Persian towns. There is a hospital of 30 beds in connexion with the shrine. Burial within the city is still carried on. During the war a good road was built from Duzdab in South-East Persia to Meshed, and it is still possible for motor traffic. Duzdab is the terminus of the railway from Quetta via Nushki. The main road from Tehran to Meshed, which carries a heavy pilgrim traffic, is not yet fit for regular motor transport. Meshed is within three days by horse-drawn vehicles of the Russian trans-Caspian railway system.

### *Public Vaccination Service.*

This vaccination service, started in Tehran in 1911, has made steady progress. It is still directed by the Sanitary Council. By 1917 the work had increased so much that it was decided to choose a director from among the members to reorganise and expand the service, and the writer was appointed and held the post until 1920. Committees, on which foreign practitioners served, were formed in the provincial capitals to superintend the local service, and ambulant vaccinators were trained and sent out to the villages. 37,000 persons were vaccinated at a cost of roughly 6d. per head. By the year March, 1924–25 the number of vaccinations had risen to 74,500, of which 52,300 were seen a second time and 47,200 returned as successful. Unfortunately it has been found impossible to appoint inspectors. Many towns and districts still have no vaccinators and send in repeated requests for them. It is entirely a question of money, and the activities of the service have of recent years been much limited by the want of it.

Up to 1922 the vaccine was obtained from France. In 1922 the newly-established Pasteur Institute at Tehran provided 35,000 doses, the first that had been made in Persia. Since then the Institute has supplied all the vaccine required, and it has been of very good quality. Arm-to-arm vaccination is still done by barbers, but reports of inoculation have not been received of recent years.

### *Hospitals.*

Although new hospitals have been opened and improvements made in existing ones since 1911, Persia is still very badly off in this respect, and foreign-supported hospitals provide most of the beds. A Government Hospital of 20 beds for women and children was opened at Tehran in 1917 under a French lady doctor. It is not equipped for major surgical work. In 1921 a military hospital of 200 beds was opened on a fine site two miles north of the city. Originally built as a hospital some 20 years before on quite sound lines, it had been used as a barracks. The staff is partly military and partly civilian, and includes a number of Russian nursing sisters. In the same year the small endowed *Vaziri hospital of 30 beds was taken over by the Government*, and the French lecturer in surgery in the medical school was put in charge. The chief civil hospital at Tehran, the "Government Hospital," of nominally 90 beds, was reorganised by British medical officers between 1919 and 1923. The British Government and the Anglo-Persian Oil Company presented a large amount of medical stores and equipment to the institution. The hospital of the American Mission (55 beds) and the dispensary of the British Legation have continued to represent foreign medical work in the capital. The Russian Hospital was closed shortly after the war.

During the past 11 years a hospital of 30 beds was opened at Meshed in connexion with the shrine, and other small hospitals at Tabriz (30 beds), Kerman, Shiraz, Enzeli, Malayer, and Shahrud. A small municipal hospital was opened at Hamadan. The needs of the provinces, however, continue to be met chiefly by the hospitals and dispensaries of the British Consulates, the Church Missionary Society, and the American Missions. The Church Missionary Society has recently opened a hospital at Shiraz and is building a women's hospital at Kerman. The American Hospital at Urumiah was unfortunately destroyed during the war; the same mission is building a hospital at Meshed at present. Finally, during recent years, the growth of the activities of the Anglo-Persian Oil Company in Southern Persia has brought the best modern medical treatment to districts and tribes where doctors did not exist, and they have not been slow to avail themselves of the benefits of well-built hospitals, X ray plants, laboratories, and dental treatment.

### *Nursing in Persia.*

The nursing of the sick presents special difficulties in a Mussulman country and has always been, and still is, a problem in Persia. Progress has, however, been made during the past 11 years through the nurses of British and American hospitals who have trained a number of girls, chiefly Armenians. Mohammedan girls were trained by the English matron of the Civil Persian Hospital at Tehran during its reorganisation, and showed great keenness and considerable capacity. The introduction of Russian sisters into the principal army hospital has been mentioned. The bulk of the nursing in Persia is, however, carried on by male orderlies of very little instruction. Midwifery has been taught in some of the foreign hospitals, and at the women's hospital at Tehran, but the old wise women still hold sway. Some of them have received elementary instruction. The village of Gulhek, where the British Legation has its summer quarters, has now a midwife of its own, a peasant woman who has received a short course of training.

The work of Persian hospitals is gravely hampered for want of funds. Special hospitals for infectious diseases and tuberculosis are badly wanted, but so are well-trained doctors and nurses.

### *Pasteur Institute.*

In 1921 the Persian Government opened a Pasteur Institute under the direction of Doctor Mesnard, of the Institut Pasteur, Paris. Laboratories were fitted up on the ground floor of the director's house and clinical examinations for practitioners and the preparation of vaccines were undertaken. Later the preparation of vaccine lymph of very excellent quality was started. The efficacy of anti-anthrax inoculation has been demonstrated by the staff on a limited scale. Serums and vaccines from Paris are distributed. At the end of 1923 rabies virus was obtained and the Institute undertook to treat cases. Rabies is rare in Persia in spite of the large number of ownerless dogs and of jackals, but the nearest places of treatment in the past had been Tiflis and, more recently, Bagdad. Instruction in bacteriology has been given to the students of the medical school.

The Institute has filled a *very big gap in medical work* at Tehran. It has, however, been badly housed and badly starved for funds. It is *capable of doing* much more important work, especially in the regions of research and of veterinary medicine. The director is to be congratulated on much good work done in the face of difficulties. Many of them will disappear when the construction (much delayed for want of funds) of the new institute with small hospital and director's house attached has been finished. The land and the water *rights* were generously given to the Government in perpetuity by H. H. Firman Firma, as well as a sum of £000.

(*To be continued.*)

---

## PROGRESS OF WESTMINSTER HOSPITAL.

THERE has been a notable increase of work and activity since the reopening of the hospital. The in-patients are 30 per cent. and the out-patient attendances 35 per cent. more than in 1922. Simultaneously subscriptions have increased by 54 and donations by nearly 100 per cent.

## HEALTH CONDITIONS IN BRITISH HONDURAS.

ACCORDING to the annual report presented by Mr. C. Douglas-Jones, Colonial Secretary, the general health of the colony during 1924 was, on the whole, good. During November three cases of yellow fever, one of which proved fatal, occurred at Stann Creek. The necessary measures were taken immediately to safeguard the capital and other districts, and the area was placed under quarantine. At the request of the International Health Board, the autopsy tissues were forwarded to them for examination. As a result of expert diagnosis the Board were of opinion that the evidence in this case did not seem to be conclusive either for or against yellow fever. There can be no doubt that the policy adopted of placing the colony in quarantine, however detrimental it may have been to its interest, was the correct course. It should be possible with an efficient medical staff and competent sanitary department, with which the colony is now equipped, to devise some scheme by which, under careful observation, suspected cases of yellow fever could be reported and placed under observation without taking the drastic steps usually adopted, which have the result of seriously dislocating the business and trade of the colony—perhaps quite unnecessarily. This question is under consideration, and the Rockefeller Foundation is being consulted. The occurrence of the enteric group of diseases in Honduras is very rare. Dr. H. B. G. Newham, of the London School of Tropical Medicine, in his report on his visit *to the colony, states that he saw a very suspicious case in* a man who had lived in Belize (the capital) for many years. The Belize Hospital returns show four cases and one death during 1924. It is probable that mild cases occur in the remote settlements. There were 33 deaths from dysentery during the year. In the Belize Hospital 16 cases of amœbic dysentery and 10 cases of bacillary dysentery were treated. There was a good deal of dysentery of a bacillary type in the town of Belize during the months of September, October, and November. House-flies were not prevalent in any part of the town during the period, and, in fact, house-flies are remarkably few there at any time of the year. The rainfall was heavy at the time these cases were occurring, and many parts of the town were swampy, and the roadside drains, where such exist, were constantly full of water. Thirty deaths from malaria were certified by medical practitioners in 1924. Among the uncertified deaths 380 were ascribed to "fever," and there is little doubt that a large majority of these was due to malaria, which also caused an unusual number of deaths, mostly among young children, in the Indian villages of San Antonio, San Pedro de Columbia, and Aguacate in the Toledo district during the months of July, August, and September. The history of these cases was very closely investigated by Dr. E. I. Vaughan, of the Rockefeller Foundation, who came to the colony in connexion with the outbreak of yellow fever in Stann Creek in November. His report endorsed the opinion of the principal medical officer that these cases were undoubtedly malaria. Pulmonary tuberculosis is prevalent. Other forms of tuberculosis are not common. Very little fresh milk is consumed in the colony, and in Belize tinned milk is universally used. In the Belize Hospital during the year there were 18 cases of all forms of tuberculosis, and of these 22 died. The vital statistics show *39 deaths from pulmonary tuberculosis, all certified* by medical practitioners. Among the uncertified deaths at least 50 were due to this malady. The estimated population of the colony on Dec. 31st, 1924, was 47,183. The *birth*-rate for the year was 38·8 per 1000, and the death-rate 23·34. The highest rainfall was, as usual, at Punta Gorda in the Toledo district, which had a total of 100·09 inches, and the lowest was at Corozal, which had a total of 30·10 inches. Belize had 59 inches. The hottest days for the year were August 23rd and Sept. 4th, on which the thermometer registered 91·50° F., and the coldest day on Nov. 18th, when it registered 57°.

## THE FUNCTIONS OF AN ARCHITECT.

THE rows of exactly similar houses which are a regrettable feature of modern England are mostly the work of independent builders. Wholesale design without intelligent regard for appearance or convenience is fortunately less common than it was, for the architect is beginning to come into his own; but many people are still at a loss to know when and why they require an architect's services, and how the fullest advantage may be taken of his skill and experience. Accordingly the Royal Institute of British Architects has prepared a pamphlet which is called "an attempt to enlighten the minds of those proposing to build regarding the duties and functions of *architects, and to explain the necessity for the engagement* of competent architects in connexion with all building work." The pamphlet is successful in doing these things in a few words, and we hope that it will be widely read. It may be obtained from the Royal Institute of British Architects, 9, Conduit-street, London, W. 1.

## THE BLIND IN GLASGOW.

According to the central register of the blind kept by the Scottish Board of Health there were in Glasgow on April 1st, 1025, the latest date for which statistics are available, 1517 blind persons in the city, exclusive of 96 of school age for whose education the education authority was responsible under the Blind and Deaf Mute Children (Scotland) Act, 1890. The present numbers probably exceed this total. More than 800 of them are over 50 years of age, and in most cases are in receipt of old age pensions. Of the remainder, 120 are under training, or are in approved institutions, and 115 have applied for technical education but have not yet been admitted to institutions.

## OCULAR COMPRESSION IN PAROXYSMAL TACHYCARDIA.

In the *Bruxelles-Médical* of Jan. 10th Dr. Pierre-Noël Deschamps describes two cases of paroxysmal tachycardia in which normal rhythm was restored on repeated occasions by pressure on the eyeball. He recommends this procedure as a method of arresting attacks, and suggests that it should be used in conjunction with quinidine, which drug, when given during periods of normal rhythm, appears to diminish the frequency of the paroxysms. The prompt response to this form of reflex vagal stimulation in the two cases quoted in this article lends force to the writer's contention that this is a procedure which deserves a trial in a condition in which we know of no certain and trustworthy remedy. Some form of vagal stimulation, either direct by pressure on the nerve-trunk in the neck or reflex by the induction of vomiting, or forced respiration, will often abort an attack. The value of drug therapy in paroxysmal tachycardia is very difficult to assess, for the tendency of the attacks to occur at irregular intervals and to terminate spontaneously makes it practically impossible to provide an efficient control, and it is only those therapeutic methods which produce an immediate effect, and can be shown to produce that effect repeatedly, that can be safely accredited in the treatment of such conditions.

## WINDOLITE.

Windolite is claimed by its makers to be a light, flexible, and practically unbreakable substitute for glass, letting through the ultra-violet rays which are stopped by ordinary glass. On account of these qualities, Windolite has, we are told, been supplied in considerable quantities to sanatoria and schools. The two samples which have been submitted to us consist of rolls of wire netting of fine mesh, the interstices of which are filled with a fairly transparent preparation. The netting is made in two grades, the mesh being practically the same in the two cases but the thickness of wire is varied so as to be nearly twice as thick in one as in the other. An examination of the transparency of these samples to the light of the iron spark spectrum shows that Windolite is more transparent to ultra-violet radiation than is ordinary window glass. There is very considerable transmission of all wave-lengths up to about 2700 A°.U., and it is well known that ordinary window glass does not, as a rule, transmit radiation of such a short wave-length as 3000 A°.U. The two samples submitted showed about the same degree of transmission, but tests made upon different portions of the same sample varied to a measurable extent, probably due to some variation in the thickness of the preparation filling the interstices.

Windolite may be obtained from the makers at 179–185, Great Portland-street, London, W. 1.

## SPA TREATMENT IN THE BRITISH ISLES.

The current issue of the *Prescriber* deals with spa treatment in the British Isles. The leading article summarises the present position in regard to spa treatment of industrial rheumatism. It has been pointed out in our columns by Dr. Fortescue Fox, of the International Society of Medical Hydrology, that a particular feature of British spas is their invigorating character, and the leading article in the *Prescriber* summarises the present position in regard to the spa treatment of industrial rheumatism. This is a subject into which the International Society of Medical Hydrology is making a special inquiry and one which has also recently received prominence in consequence of the statement of Sir George Newman, the Chief Medical Officer to the Ministry of Health, that something like £2,000,000 is being spent annually in the treatment of the rheumatic group of diseases among insured persons, while the time lost to industry through such diseases amounts to 3,000,000 weeks or 60,000 years. Dr. Fortescue Fox, in dealing with the inter-relation of British spas as health centres, believes that "the time is not far distant when not the spas only, but all other centres along the coast where adequate external treatment can be given . . . . will make their own particular contributions to the prevention and cure of disease." Special articles deal with the history of Buxton, the development of F

Droitwich, and Trefriw in Carnarvonshire. Many
reproduced illustrations add to the interest of a collect
details about our British spas which is valuable for refe

## DR. TIMOTHY BRIGHT AND SHORTHAND

At the sale of Britwell Court Library at Sotheb
March 15th one of the only two known copies
Timothy Bright's book on shorthand was sold for
to the agent of Dr. Abraham Rosenbach, the well-
bibliographer, of Philadelphia. Timothy Bright's nam
recently recalled (The Lancet, Feb. 27th, p. 475)
article on Medical Inventors. He graduated in medic
Cambridge in 1579. Nine years later his book,
"Characterie, an Arte of Shorte, Swifte, and S
Writing by Character," was published in London
a dedication to Queen Elizabeth. Timothy Bright's s
consisted of 18 symbols, with four slopes for each lette
12 different ways of altering the base, so that each
could represent 18 words. It was necessary for the st
to learn by heart the signs for 537 words. The other
of Bright's book is in the Bodleian Library.

## LIVERPOOL HOSPITALS.

At the annual meeting of the Royal Southern Ho
Liverpool, on March 8th it was reported that th
had now reached the serious figure of over £26,00
department may possibly have to be closed down.
the annual meeting of the Royal Liverpool Chil
Hospital the following day it was announced that i
was falling short of expenditure by about 10 per

benefits"; and there is no doubt that this expre
widely accepted view and one which vitally affect
position of all honorary members of the medical
The Children's Hospital has in view large extension at
of the main branches of the institution. At Heswa
nurses' home is being extended and new open-air
accommodating in all a further 90 patients, are in imm
prospect. At the city branch the new building, prov
further housing for nurses as well as new quarters fo
resident medical staff, is on the point of completion.

## INFECTIOUS DISEASE IN ENGLAND AND WA DURING THE WEEK ENDED MARCH 6TH, 19

*Notifications.*—The following cases of infectious di
were notified during the week:—Small-pox, 109 (last
202); scarlet fever, 1643; diphtheria, 1171; e
fever, 39; pneumonia, 1212; puerperal fever, 47; ce
spinal fever, 12; acute poliomyelitis, 5; acute
encephalitis, 1; encephalitis lethargica, 52; dysenter
ophthalmia neonatorum, 109. There were no cas
cholera, plague, or typhus fever notified during the we

The notified cases of small-pox were fewer by 93 th
the previous week. Since this return was made up a
case of small-pox, the first since May of last year, has
reported from Cambridge. Dr. A. J. Laird, medical o
of health for the borough of Cambridge, informs us
the victim was a school-girl, aged 13½ years, who had
been vaccinated. She sickened on March 5th whils
school, and the eruption appeared on March 8th. She
seen on the evening of March 9th, and removed to hos
at once. She died on the following night. There was
eruption of papules, some of which contained blood, on
soles of the feet, where there were about two dozen s
on each, and on the palms of the hands, where there
nearly a dozen spots on each. There was little else on
body or on the face. There was some hæmorrh
(subcutaneous) on one buttock, and from the nose, and
subconjunctival hæmorrhage. The patient was se
comatose from the time of admission to hospital until de
It is interesting to note that the parents, who had both
vaccinated (the mother in infancy and the father in inf
and while in the army), were not conscientious objec
Both their children, however, were unvaccinated.

A recent report of the medical officer of health for S
Shields states that among recent cases of small-pox i
district were some of confluent type, likely to
permanent disfigurement.

*Deaths.*—In the aggregate of great towns, including Lon
there were 2 (0) deaths from enteric fever, none
small-pox, 102 (40) from measles, 8 (3) from scarlet f
59 (9) from whooping-cough, 48 (13) from diphth
40 (10) from diarrhœa and enteritis under 2 years of
and 97 (12) from influenza. The figures in parent
are those for London itself. For the fifth time during
last seven weeks the deaths from measles exceed 100.
mortality from influenza is still practically stationary.
